

# Hyper-Kamiokande and proton decay

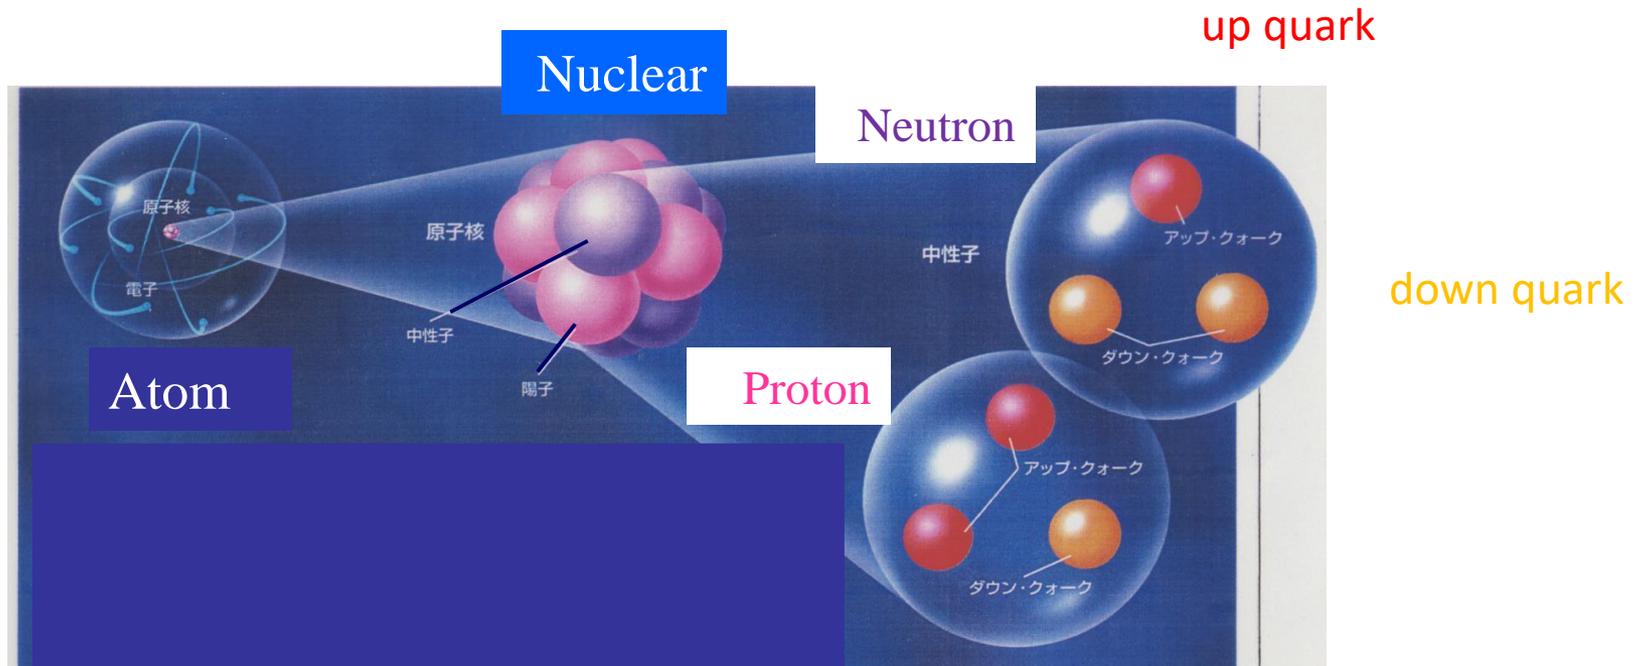

2024/07/22

M.Miura

Kamioka observatory, ICRR, UTokyo

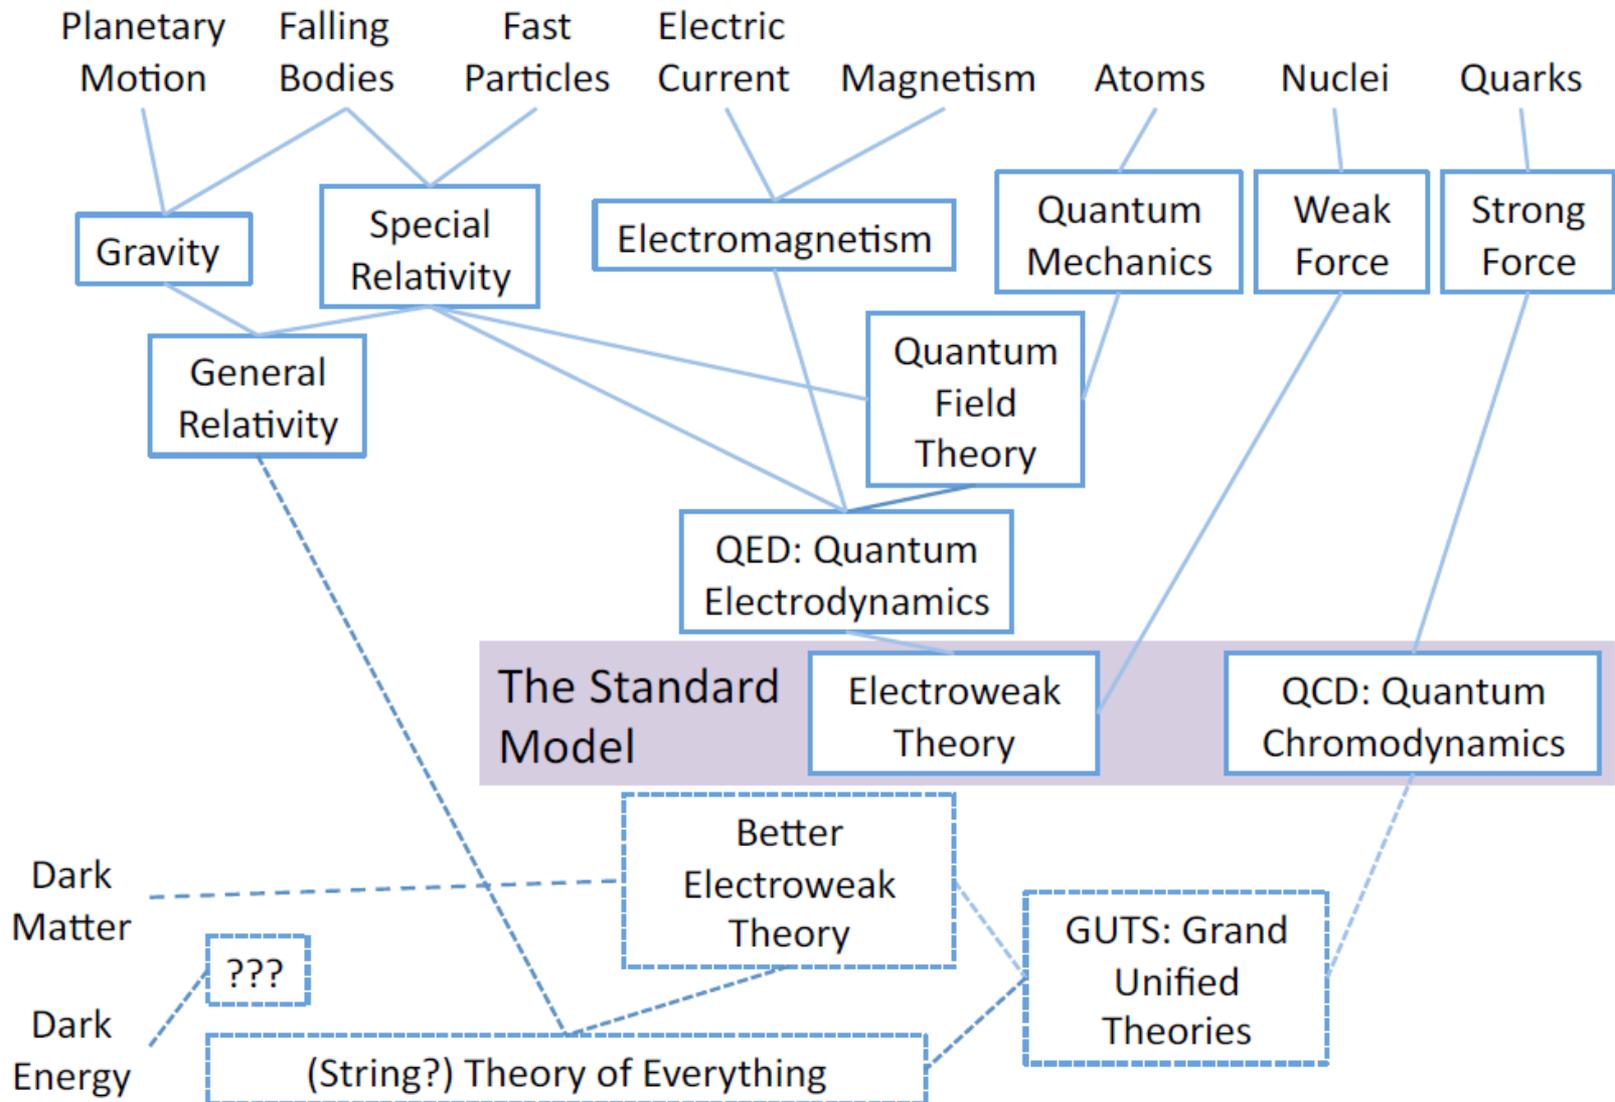

# 1. Does Proton Decay ?

- Nucleus consists of protons and neutrons.

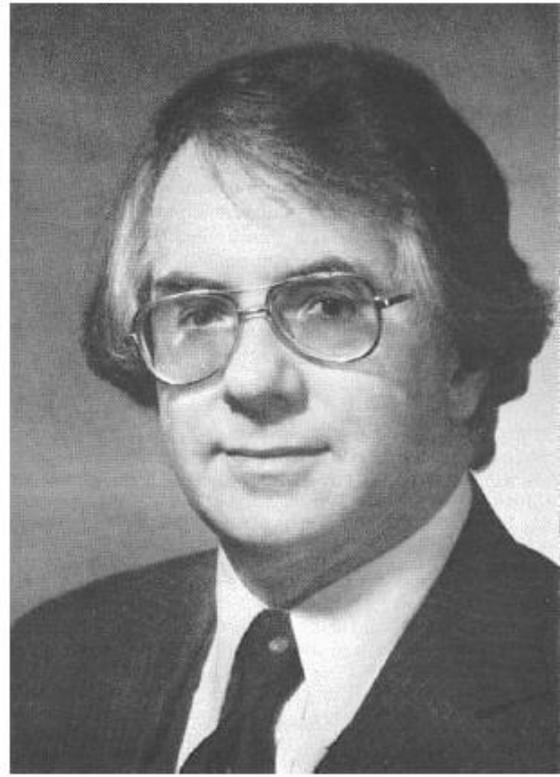

- It is well known that neutron decays spontaneously as  $\beta$ -decay:  $n \rightarrow p + e^- + \bar{\nu}_e$ 
  - Note that  $M_n > M_p$ .
- People thought proton is stable because of baryon number conservation.
  - n,p has baryon number 1.
  - We have never observed phenomena with baryon number violation.
  - Proton is the lightest baryon in the world.
  - 1929: Weyl suggests absolute stability of proton
- But is it really true ?

# Can we explain everything by a single theory ?

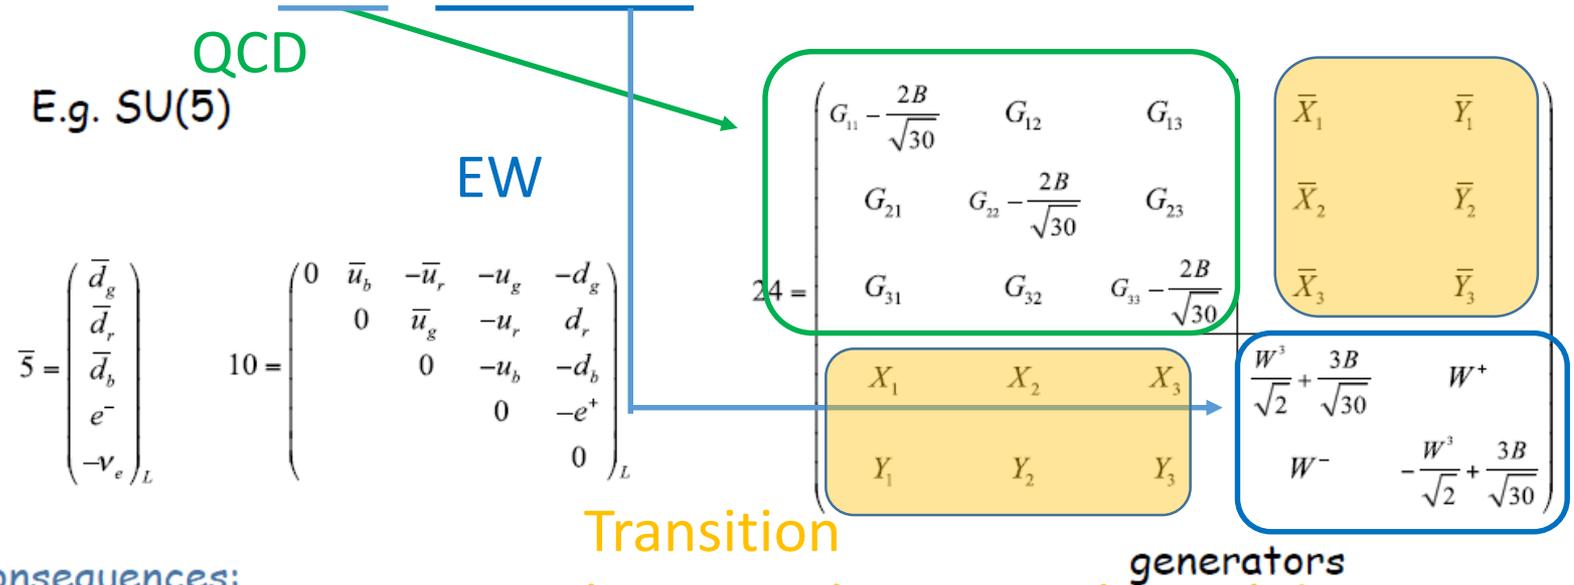

**SU(5) by Georgi and Glashow (1974)**

# Grand Unified Theories

Assume  $SU(3) \otimes SU(2) \otimes U(1)$  is part of a larger symmetry group

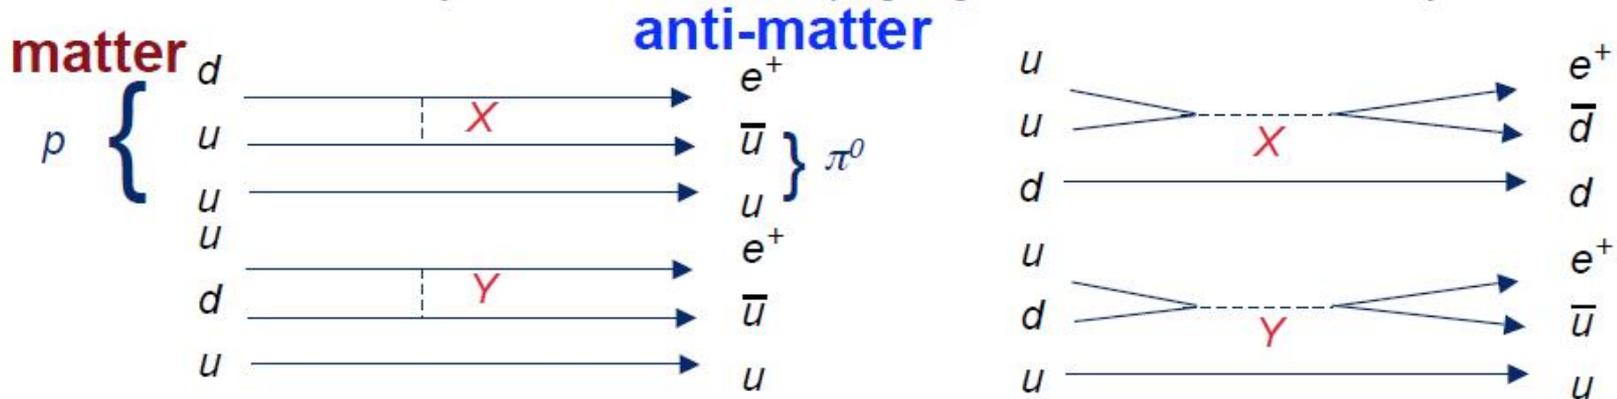

Consequences:

- ◆ Single (unified) coupling
- ◆ Charge quantization:  $Q_d = Q_e/3, Q_u = -2Q_d \Rightarrow Q_p = -Q_e$
- ◆ New gauge interactions ( $X, Y$  bosons)  $\Rightarrow$  proton decay

# Proton Decay in SU(5) By Georgi and Glashow (1974)

- Decay mechanisms

dominated by the dimension=6 op. gauge boson mediated decays

( $X^{\pm 4/3}, Y^{\pm 1/3}$  : new gauge bosons)

- Predictions

$$\tau/B (p \rightarrow e^+ \pi^0) = 4 \times 10^{29 \pm 1.7} \text{ years}, B(p \rightarrow e^+ \pi^0) \approx 40 \sim 60 \%$$

$p \rightarrow e^+ \pi^0$  became the most famous and popular decay mode.

## 2. How to find proton decay

- Watch a proton for very long time ( $> 10^{30}$  years).
  - Age of the universe:  $\sim 10^{10}$  years
  - Obviously impossible.

OR

- Watch many protons for (relatively) short time.
  - Lifetime  $\tau$ :  $N(t) = N(t=0)\exp(-t/\tau)$
  - **Need huge detector !**

# Proton Decay Detectors

IMB

H<sub>2</sub>O

Kamiokande

H<sub>2</sub>O

H<sub>2</sub>O

Super-Kamiokande

Fe

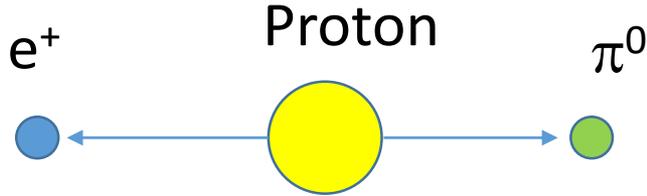

Soudan

Higher sensitivity in Water Cherenkov Detectors

2. Dominant decay mode:

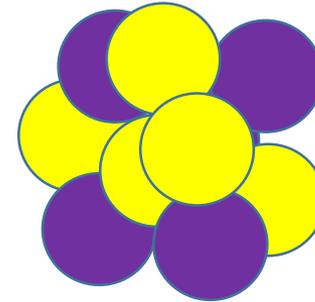

$$\rho \rightarrow e^+ \pi^0$$

# What's important for $p \rightarrow e^+ \pi^0$ ?

In "free" proton case,  $e^+$  and  $\pi^0$  emit in back-to-back. Energy corresponding to proton mass is fully used.

Nucleus

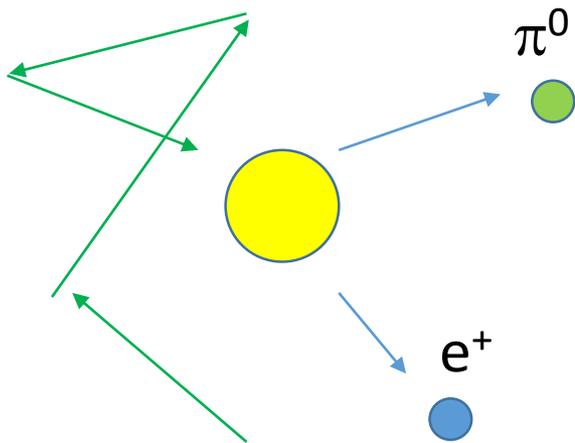

What happens if a bound proton in nucleus decays ?

Inefficiencies and uncertainties of proton decay search come from nuclear effect !

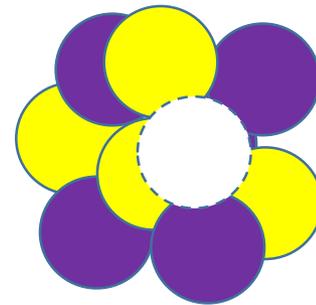

Key 1: Proton never stops in nucleus

- Protons don't exist locally in nucleus. It is always moving in the nuclear potential (Fermi motion,  $p_f \sim 225$  MeV/c).

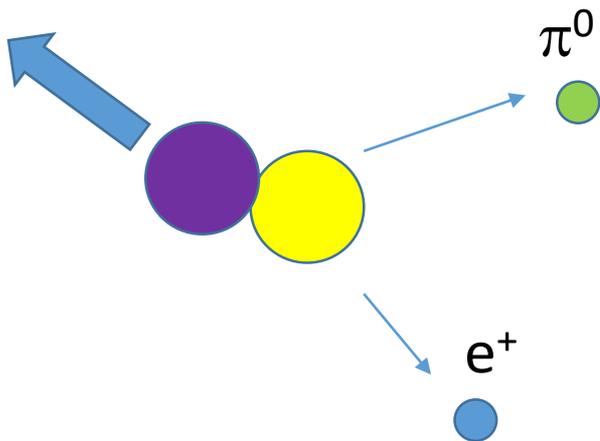

Key 2: Binding energy

- Energy corresponding proton mass should be used for compensating its binding energy (s-state:  $\sim 40$  MeV, p-state: 15 MeV in Oxygen).

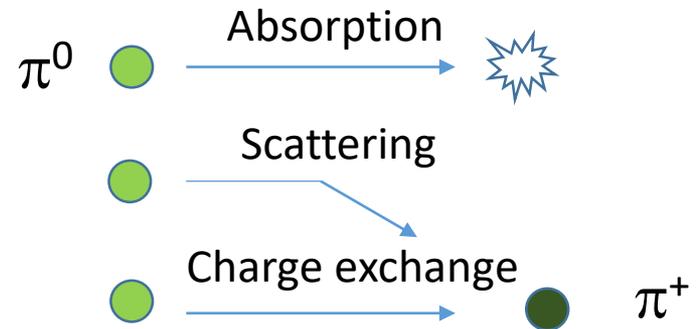

Key 3: Proton strongly binding to other nucleus

- ~ 20% protons are strongly binding to other nucleon which also bring energy when the proton decays (correlated decay)

Key 4:  $\pi$  interacts in nucleus

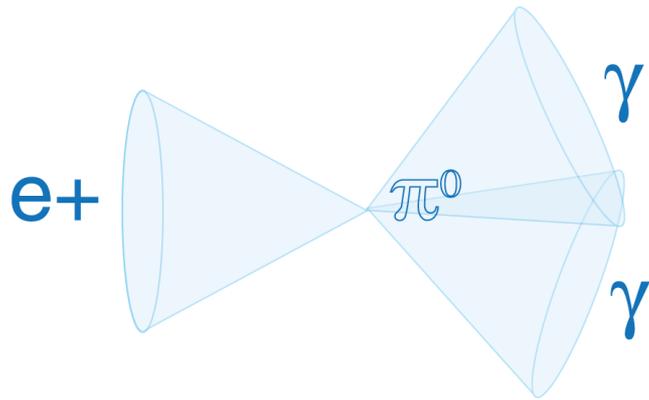

- Mesons ( $\pi, K$ , e.t.c.) in decay products are affected in nuclear interactions before exiting nucleus.

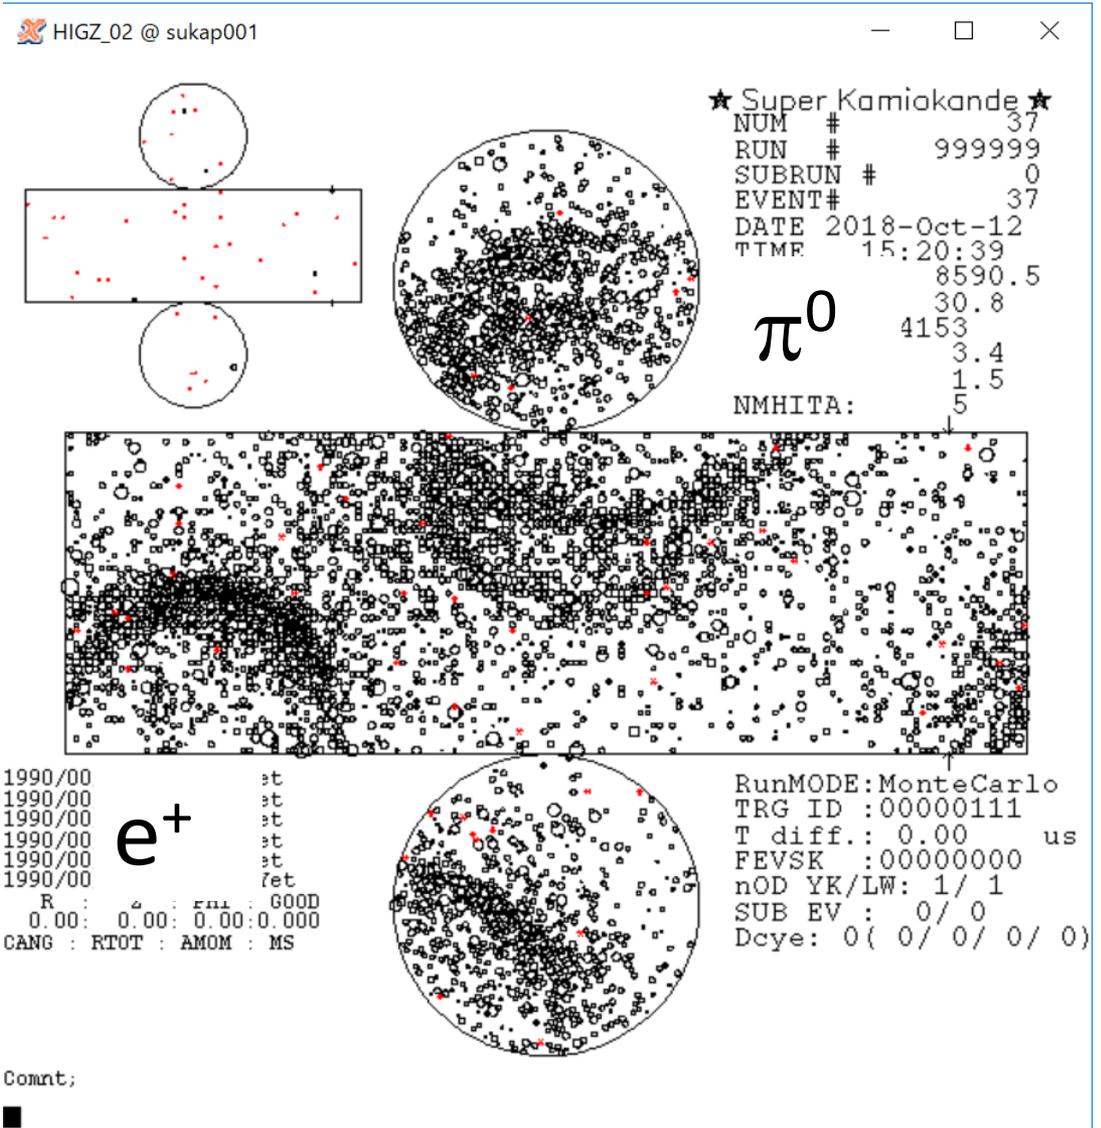

# Why water is used for proton decay search ?

- **Easy to construct larger detector.**
  - Much cheaper than iron.
  - You can find large water tank everywhere (common technology).
- **High efficiency and low uncertainty.**
  - H<sub>2</sub>O has two hydrogens which are not affected by nuclear effect . They are regarded as “free” proton.
    - ✓ Bound proton:  $\sim 200 \text{ MeV}/c \sim 0.2c = 6 \times 10^7 \text{ m/s}$
    - ✓ velocity of molecular in liquid  $\sim 10^2 \text{ m/s}$
  - **Free protons contribute high selection efficiency and low uncertainty.**

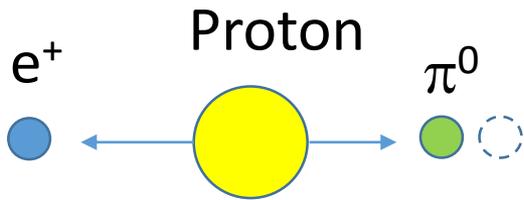

# How look like $p \rightarrow e^+ \pi^0$ in SK ?

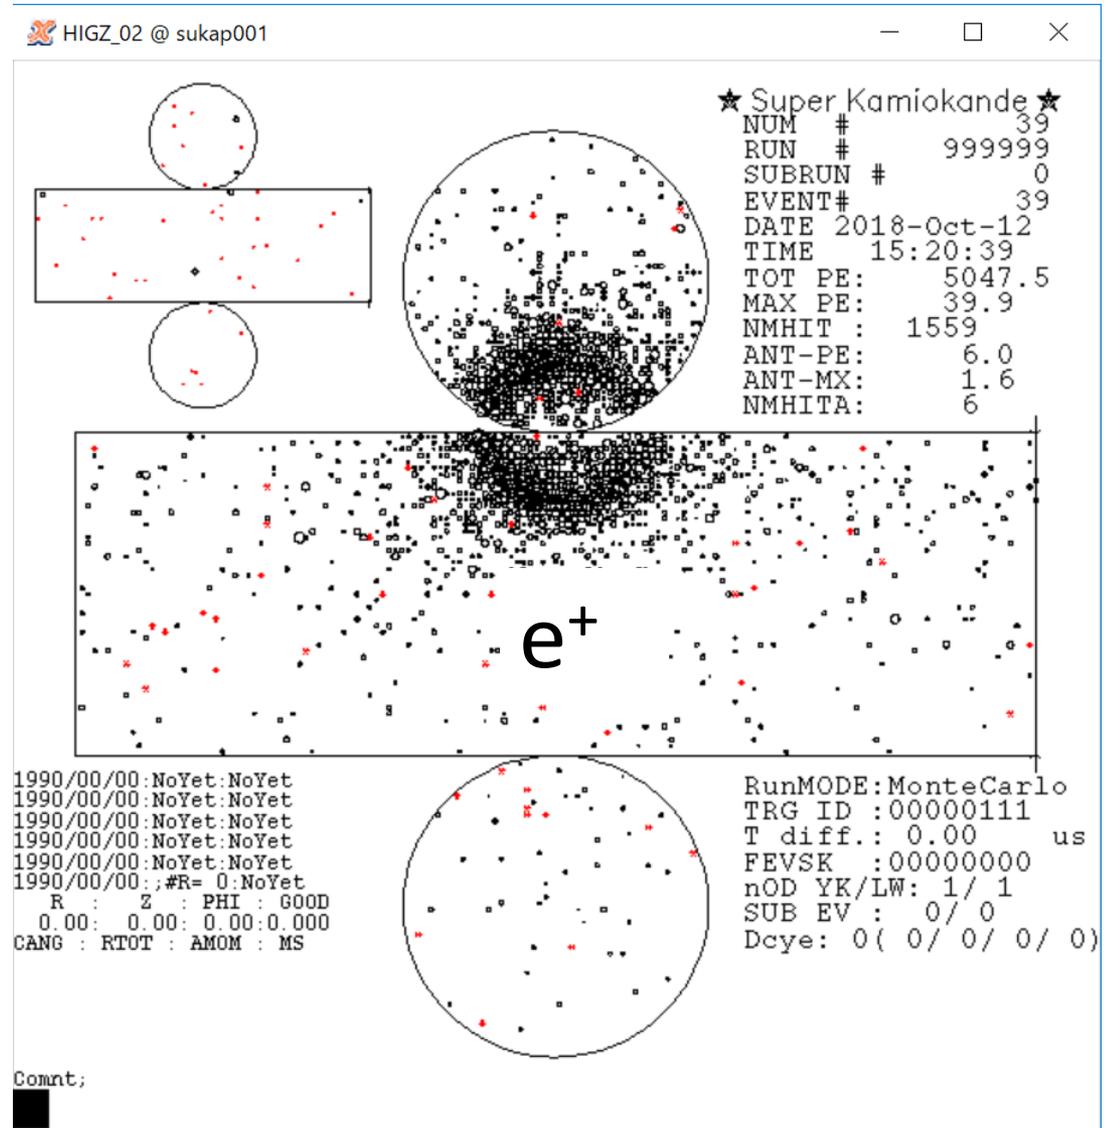

Three e-like rings should be observed.

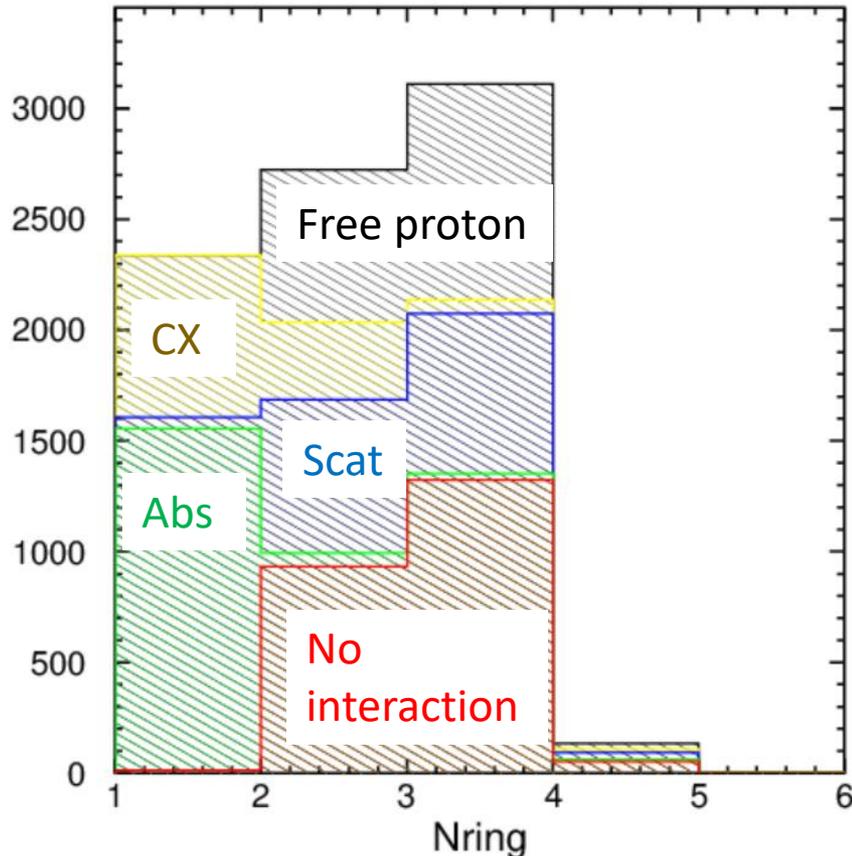

If  $\pi^0$  is absorbed before exiting nucleus, only  $e^+$  is observed (one ring).

# Observed number of ring for $p \rightarrow e^+ \pi^0$

Free proton: H in H<sub>2</sub>O

No interaction in Nucleus

Abs:  $\pi^0$  absorption in Nucleus

Scat: scattered

CX: charge exchange

( $\pi^0 \rightarrow \pi^\pm$ , below threshold)

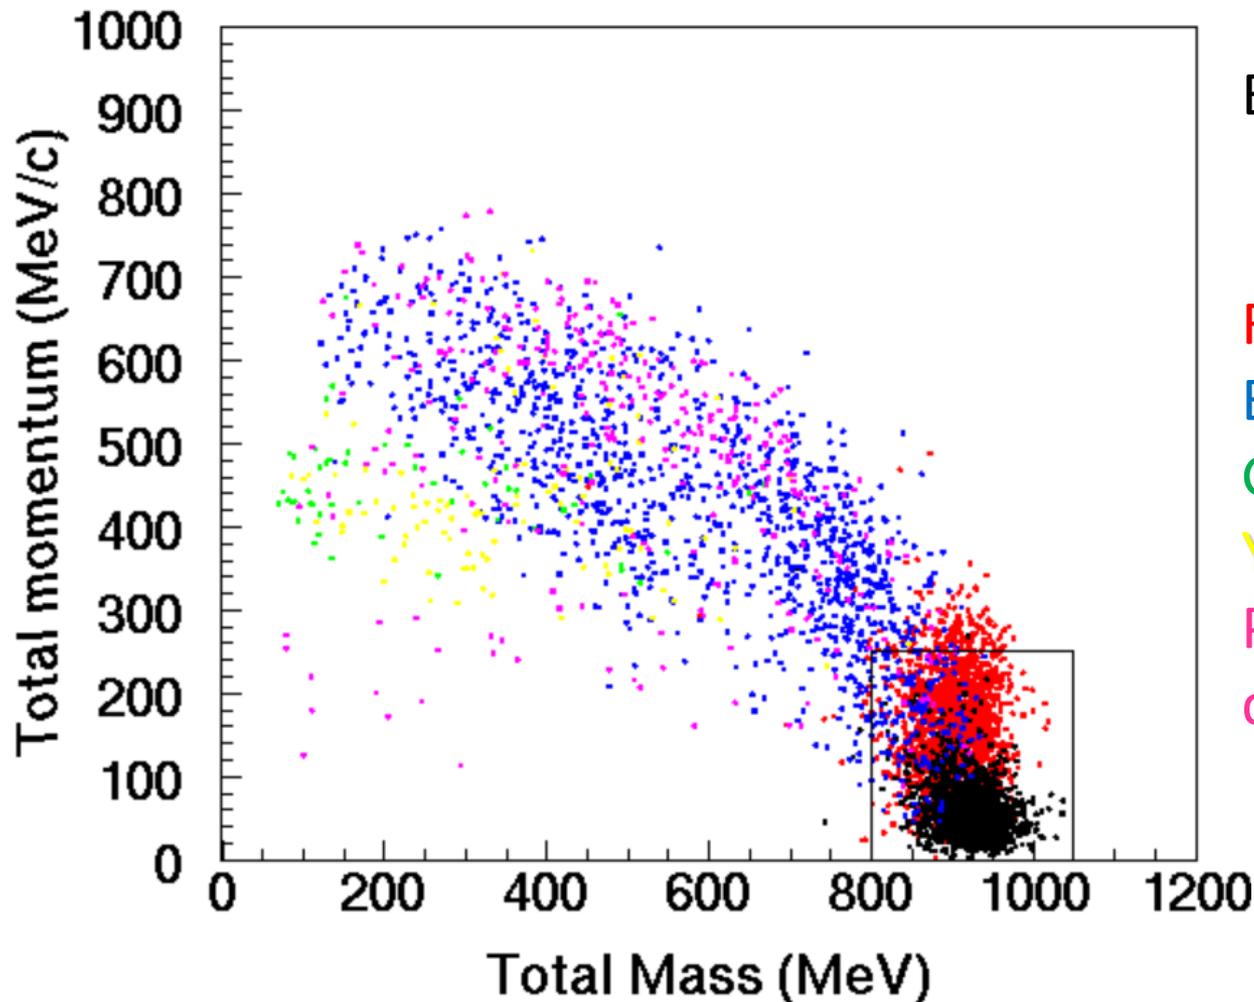

Choose 2 or 3 rings.

# Selection criteria for $p \rightarrow e^+ \pi^0$

1. Event vertex should be located 1 m inward from the tank wall (fiducial volume cut, [27.2kton](#)).
2. 2 or 3 ring event.
3. All ring should be e-like (Particle IDentification).
4. No Michel electrons.
5. Reconstruct  $\pi^0$  mass for 3 ring events. It should be  $85 < M_{\pi^0} < 185 \text{ MeV}/c^2$
6. Reconstruct total mass and momentum should be  $800 < M_{\text{tot}} < 1050 \text{ MeV}/c^2$ ,  $P_{\text{tot}} < 250 \text{ MeV}/c$ .

# Total mass vs Total momentum for $p \rightarrow e^+ \pi^0$

- Selection efficiency  $\sim 40\%$
- Inefficiency is dominated by unavoidable physics processes.

Black: Free proton

Brown: Bound proton

Red: No  $\pi$  interaction

Blue:  $\pi$  scatter

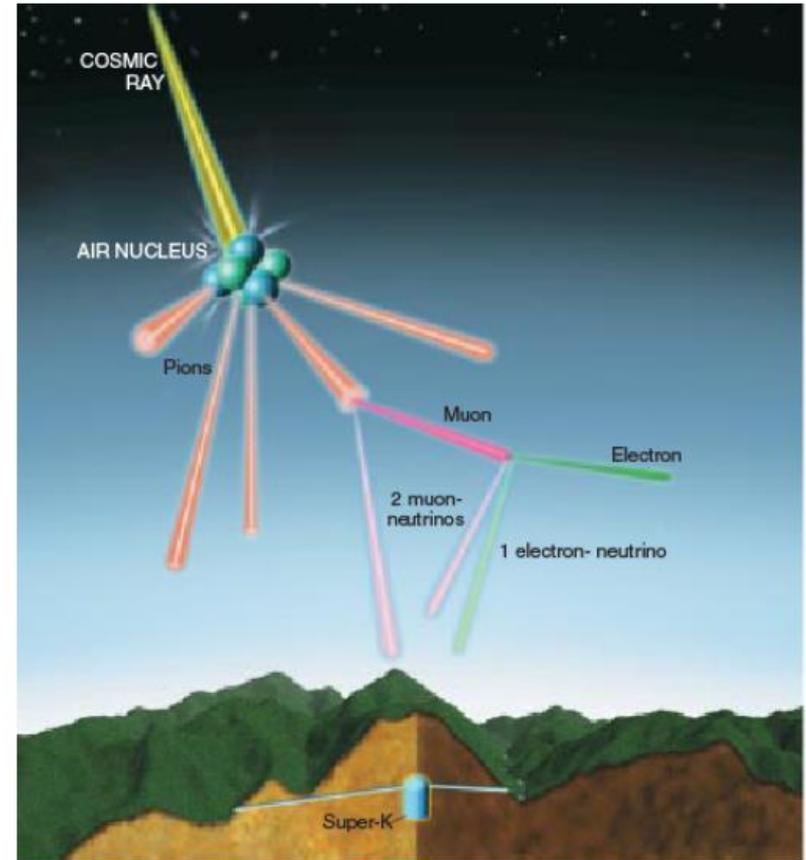

Green:  $\pi$  absorption

Yellow:  $\pi$  CX

Purple: Correlated decay

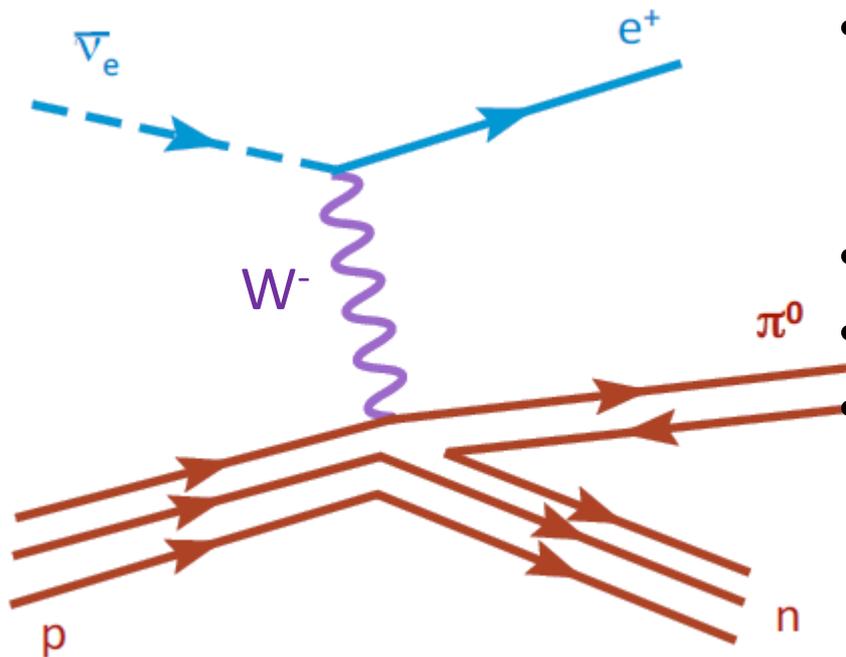

## 2-2. What's Background events for proton decay searches ?

- **Atmospheric neutrino** is dominant backgrounds for proton decay searches.
  - Visible energy  $\sim 1$  GeV.
  - Solar or SN  $\nu$  is too low energy.
  - Cosmic ray  $\mu$  are rejected by outer detector.

# Typical background for $p \rightarrow e^+ \pi^0$

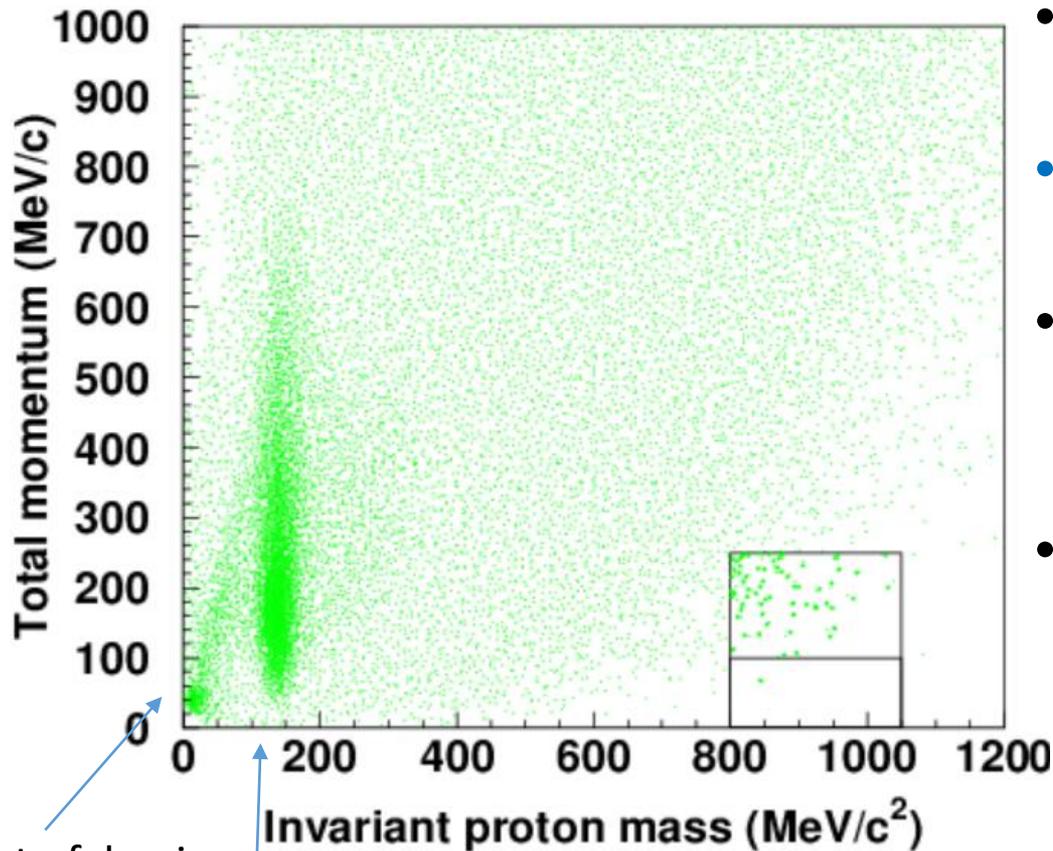

## Charged current $\pi^0$ production

- Exchange  $W$  boson between  $\nu$  and proton (charged current interaction).
- $\nu$  changes to  $e^+$ .
- $\pi^0$  and neutron are produced.
- Because neutron doesn't emit Cherenkov light, visible particles after the reaction are same as  $p \rightarrow e^+ \pi^0$

# Total mass vs Total momentum for atmospheric $\nu$ background MC

(After all cuts except for total mass and momentum)

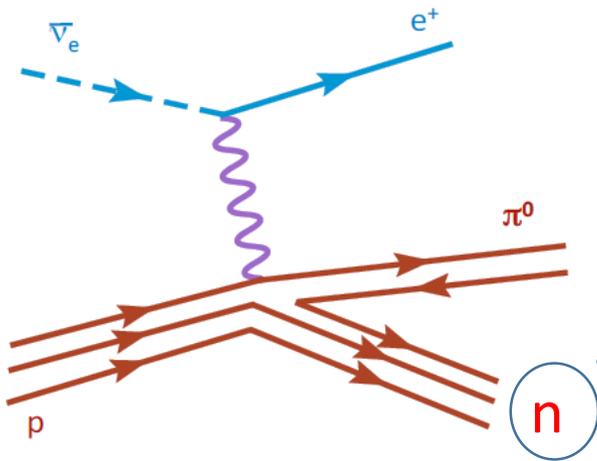

Due to fake ring

$\pi^0$  due to  $2Re+e$  is allowed.

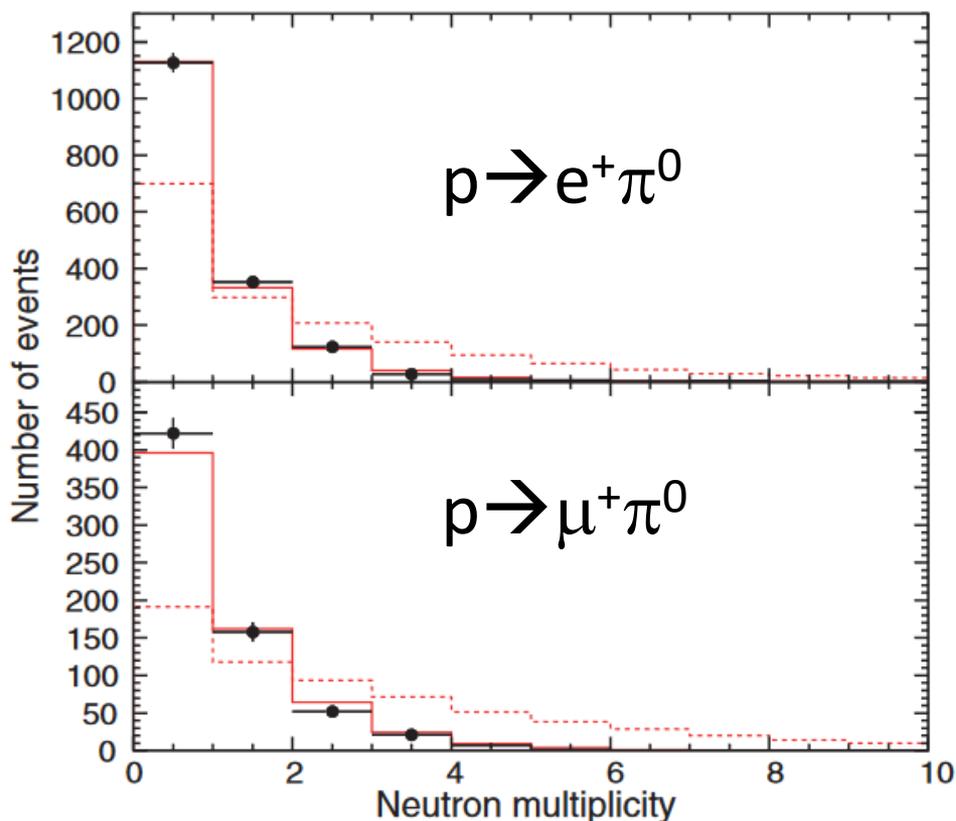

- Generate huge atm.n MC, 2000 year of SK!
- Expected BG:  
 $\sim 1.3 \text{ ev/Mton*yr}$
- Neutrino events tend to have higher total momentum.
- Almost background free in lower momentum region ( $< 100 \text{ MeV/c}$ ).
  - The region corresponds to free proton decay.

# Further background reduction

- Neutron doesn't emit Cherenkov light.
- However, neutron is thermalized in water and finally captured by hydrogen ( $\sim 200 \mu\text{s}$ );  
$$n + p \rightarrow d + \gamma (2.2 \text{ MeV})$$
- If we can detect delayed 2.2 MeV  $\gamma$  ray, we can reduce background more.
- Neutron capture is also important for SN Relic  $\nu$  and separate  $\nu$  and  $\bar{\nu}$  interactions in atmospheric  $n$  oscillation analysis.

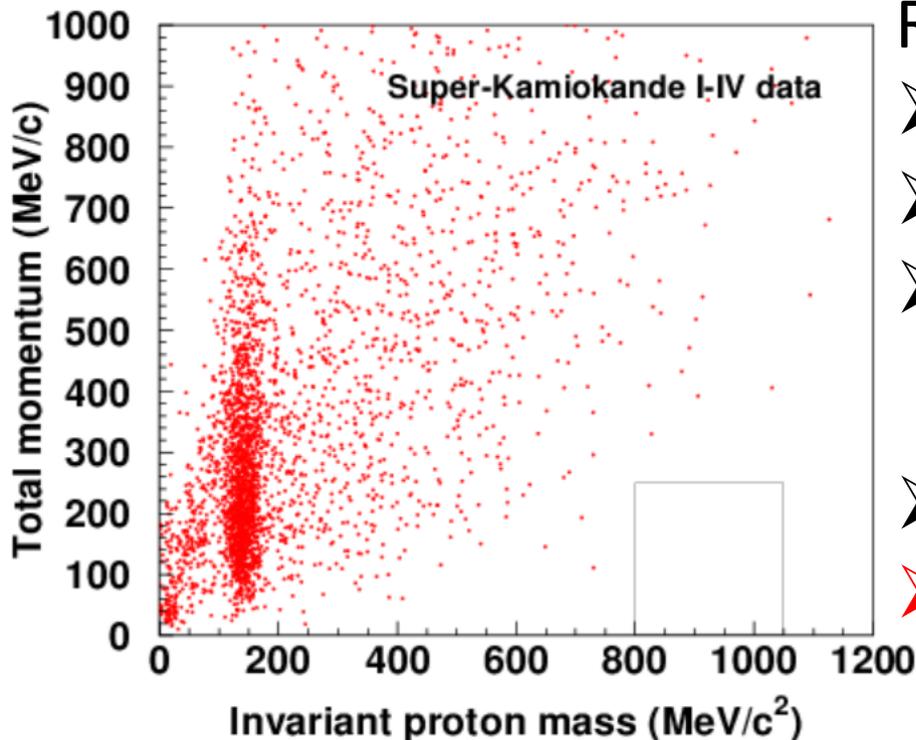

# How powerful to reject background

- Sample: out of signal box in  $M_{\text{tot}}$  vs  $P_{\text{tot}}$  plot.
  - Dot: data,
  - **Histogram: Atm.  $\nu$  MC**  
(solid: reconstructed, dash: true)
- **~ 50 % background events are rejected** with neutron=0.
- On the other hand, ~ 7.5 % of  $p \rightarrow e^+ \pi^0$  are accompanied with neutron from deexcitation of nucleus. Neutron tagging **reduces a few % in selection efficiency.**

## 2-3. SK result (so far)

- We have not find any evidences of nucleon decays !

Result of  $p \rightarrow e^+ \pi^0$

- Exposure: 450 kton · year
- Efficiency: 38.6 % (SK-IV)
- Expected BG: 0.63 events
  - 0.05 evetns in  $P_{\text{tot}} < 100 \text{ MeV/c}$
  - 0.58 events in  $100 \sim 250 \text{ MeV/c}$
- Observed: 0 event
- Lower limit of proton life time:  $> 2.4 \times 10^{34}$  years

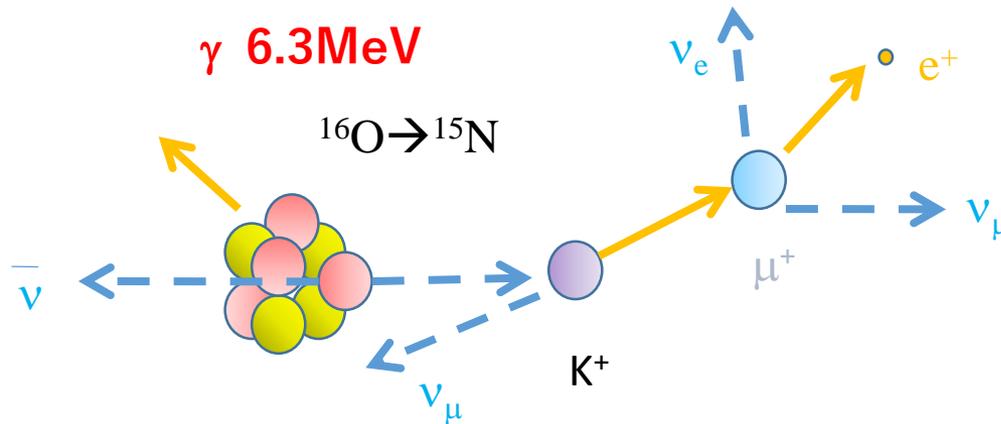

3. SUSY favored decay mode:

$$p \rightarrow \nu K^+$$

# 3-1 How to find $p \rightarrow \nu K^+$ in Water Cherenkov detector

- $K^+$  has low momentum, most of them **stop in water** and decay with 12 nsec lifetime.
- Major  $K^+$  decay mode
  - $K^+ \rightarrow \nu\mu^+$  : 64 %
  - $K^+ \rightarrow \pi^+\pi^0$ : 21 %
- “Stopping  $K^+$ ” means **two body decay products of  $K^+$  should have monochromatic momentum.**
  - $K^+ \rightarrow \nu\mu^+$  : 236 MeV/c
  - $K^+ \rightarrow \pi^+\pi^0$ : 206 MeV/c
- Using this property, Water Cherenkov detector can search for  $p \rightarrow \nu K^+$  .

## 3-2. Search for $p \rightarrow \nu K^+$ , $K^+ \rightarrow \nu \mu^+$

- Visible particle is only  $\mu^+$  with Michel electron.
- Search for data excess around 236 MeV/c of  $\mu$  comparing with atmospheric  $\nu$  MC.
- After proton decay, **40 % of remaining nucleus emits 6 MeV  $\gamma$  for deexcitation.** It is useful to reduce background.

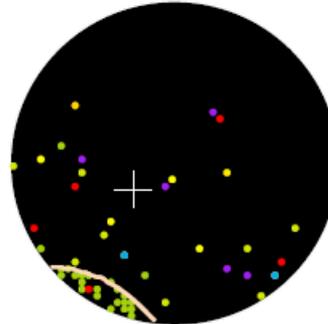

# Example of $p \rightarrow \nu K^+$ , $K^+ \rightarrow \nu \mu^+$ with $\gamma$

## Super-Kamiokande IV

Run 999999 Sub 0 Event 69  
D\_wall: 1165.1 cm  
Evis: 53.2 MeV  
mu-like,  $p = 231.0$  MeV/c

### Resid (ns)

- -68- -45
- -91- -68
- -114- -91
- -137--114
- <-137

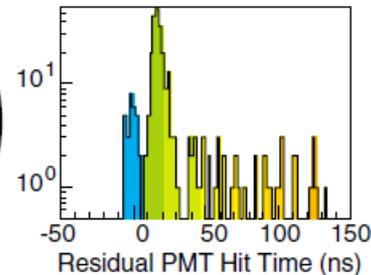

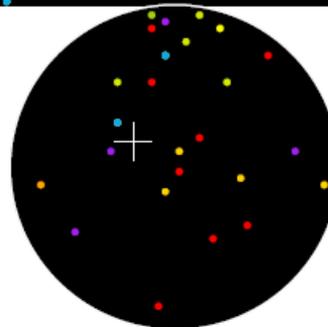

Color of hits corresponds to time.

Cyan corresponds to nuclear  $\gamma$ .

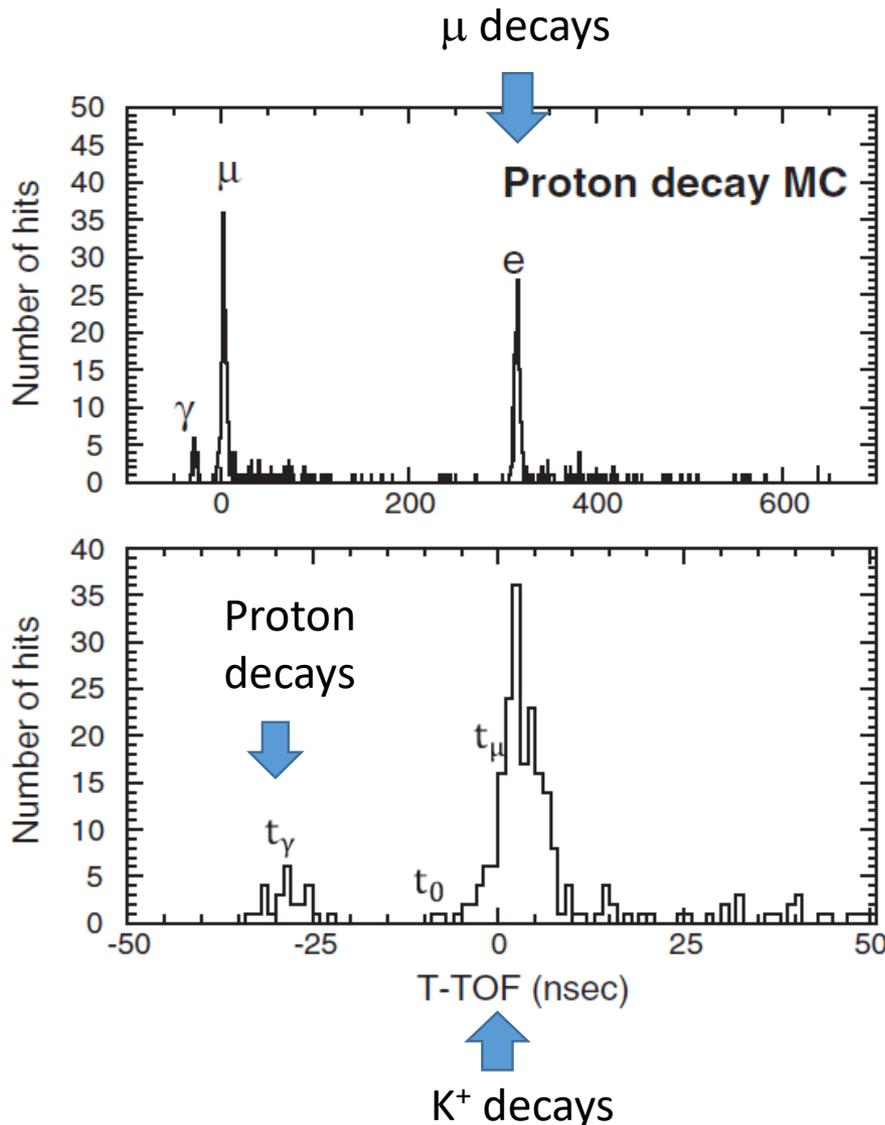

$\mu$

Difficult to identify  $\gamma$  from hit pattern.

# Time structure with nuclear $\gamma$

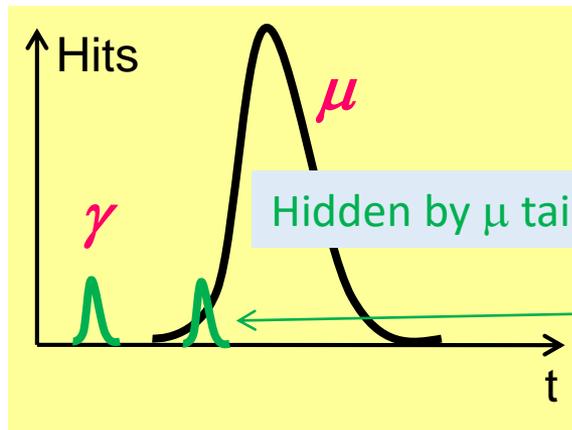

- 3 hit clusters in time should be observed in case of signal.
- The event is triggered by  $\mu$  hits.
- $\gamma$  signal is much smaller than  $\mu$  and easily hidden by tail of  $\mu$  hits.
- Make 12 nsec time window and slide it toward left from  $t_0$  (end of  $\mu$  tail) to search for maximum hit cluster.

# Selection criteria for $p \rightarrow \nu K^+$ , $K^+ \rightarrow \nu \mu^+$

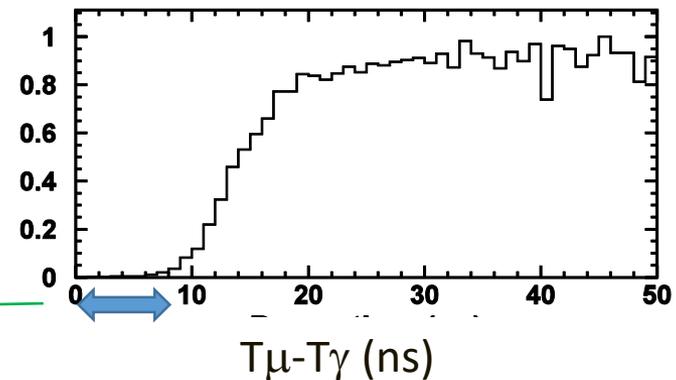

- 1  $\mu$ -like ring with Michel electron
- $215 < P_\mu < 260$  MeV/c
- Proton rejection cuts
- Search Max hit cluster  Reduce background by  $5 \times 10^{-4}$  !  
by sliding time window (12ns width);
  - $4 < N_\gamma < 30$  hits
  - $T_\mu - T_\gamma < 75$  nsec
- No neutron
- Selection efficiency = (selected events)/(proton decay in fiducial volume):  
9 %
  - $\text{Br}(K^+ \rightarrow \nu \mu^+) = 64$  %, only 40 % emits nuclear  $\gamma \rightarrow 26$  %  
even if detector is perfect.

# Remark for this analysis

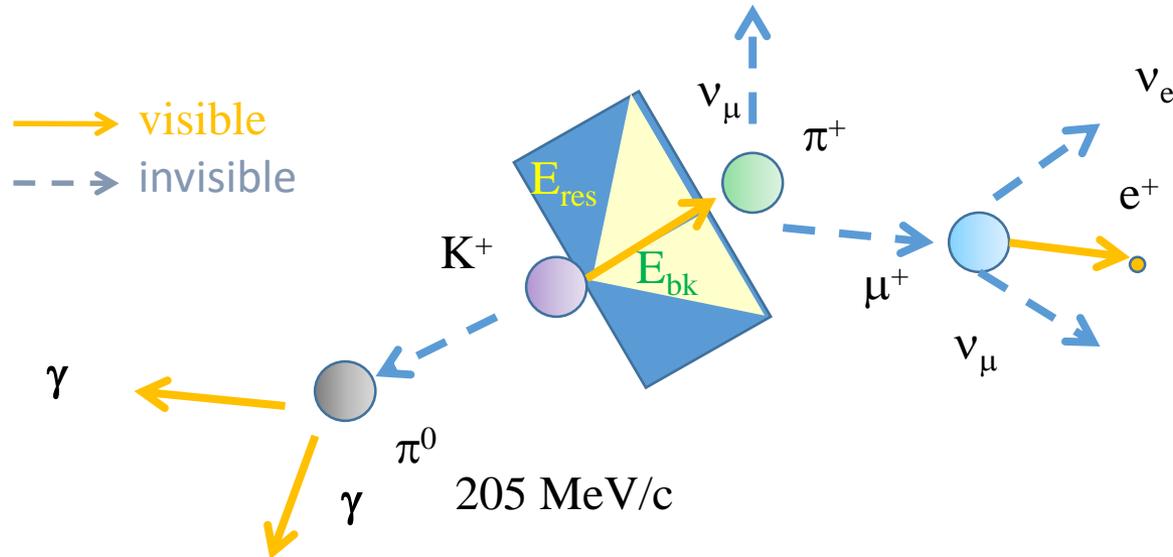

- This analysis is limited by time resolution of PMTs.
  - If  $\gamma$  is close to  $\mu$ ,  $\gamma$  peak is hidden by  $\mu$  hits.
  - Time resolution of SK PMT is 2.2 nsec at 1 photoelectron.
  - If  $\mu$  peak becomes sharper, the selection efficiency will be improved.

$\gamma$  tagging efficiency

### 3-3. Search for $p \rightarrow \nu K^+$ , $K^+ \rightarrow \pi^+ \pi^0$

- Both  $\pi^+$  and  $\pi^0$  has **205 MeV/c** in momentum. This is just above Cherenkov threshold for  $\pi^+$ , thus it is not identified as a ring in most of case.
- $\pi^+$  decays into  $\mu$  (invisible) and  $\nu$ ,  $\mu$  decays into  $e \nu_e \nu_\mu$ .
- $\pi^0$  decays into 2  $\gamma$ s.
- Search for 206 MeV/c  $\pi^0$  with Michel electron.

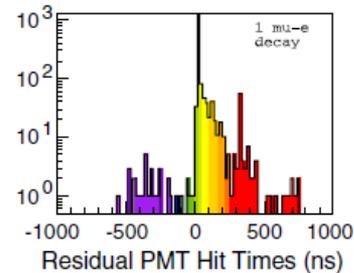

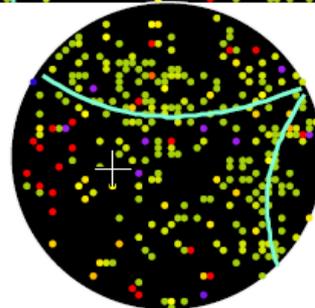

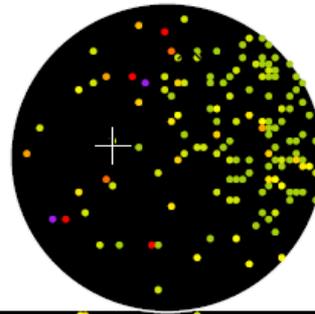

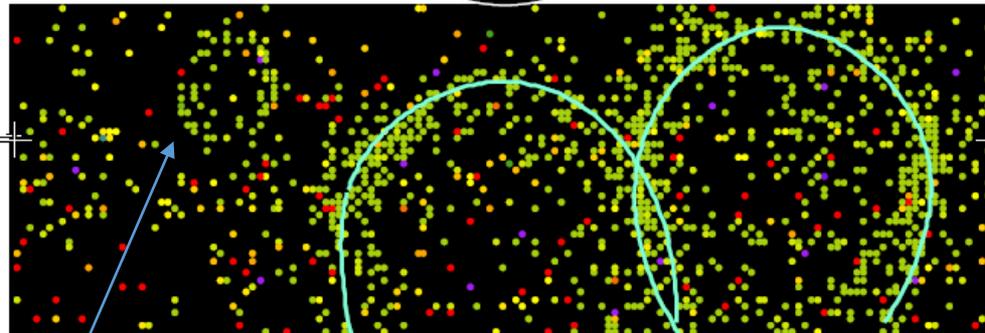

# Example of $p \rightarrow \nu K^+, K^+ \rightarrow \pi^+ \pi^0$

# Use $\pi^+$ information to select events

Charge distribution

Zoom

B) Make likelihood for hit pattern.

$\pi^+$  direction

# Selection criteria for $p \rightarrow \nu K^+, K^+ \rightarrow \pi^+ \pi^0$

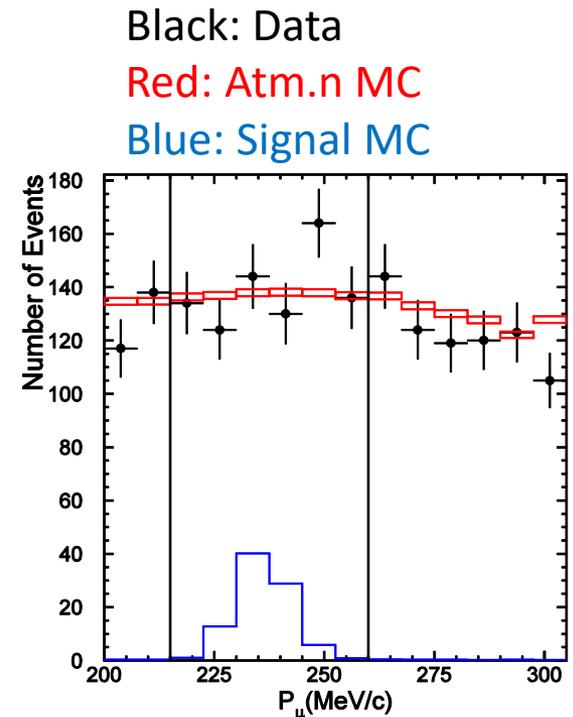

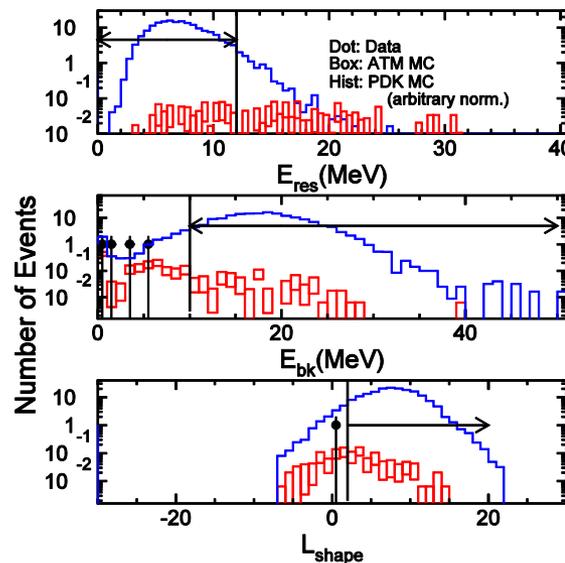

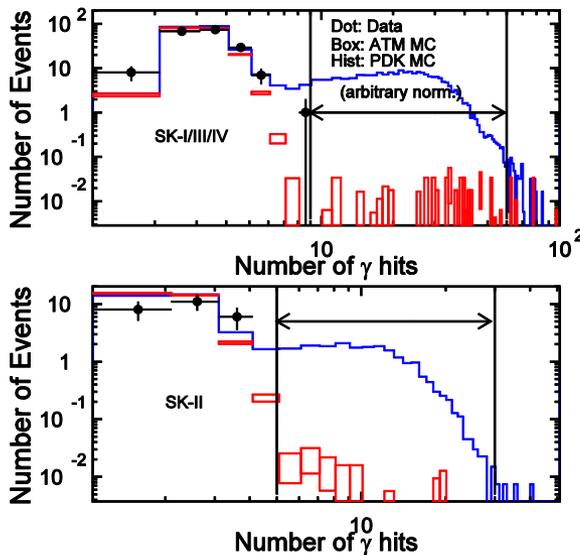

- 1 or 2 e-like rings with decay-e.
- $85 < M_{\pi^0} < 185$  MeV.
- $175 < P_{\pi^0} < 250$  MeV/c.
- $E_{bk}$ : visible energy sum in 140-180 deg. of  $\pi^0$  dir,  
 $E_{res}$ : in 90-140 deg,  
 $L_{shape}$ : Likelihood based on charge profile
  - $10 < E_{bk} < 50$  MeV
  - $E_{res} < 12$  MeV (20 MeV for 1ring)
  - $L_{shape} > 2.0$  (3.0 for 1ring)
- No neutrons
- Selection efficiency: 10 % ( $Br(K^+ \rightarrow \pi^+ \pi^0) = 21$  %)

# Background for $p \rightarrow \nu K^+$

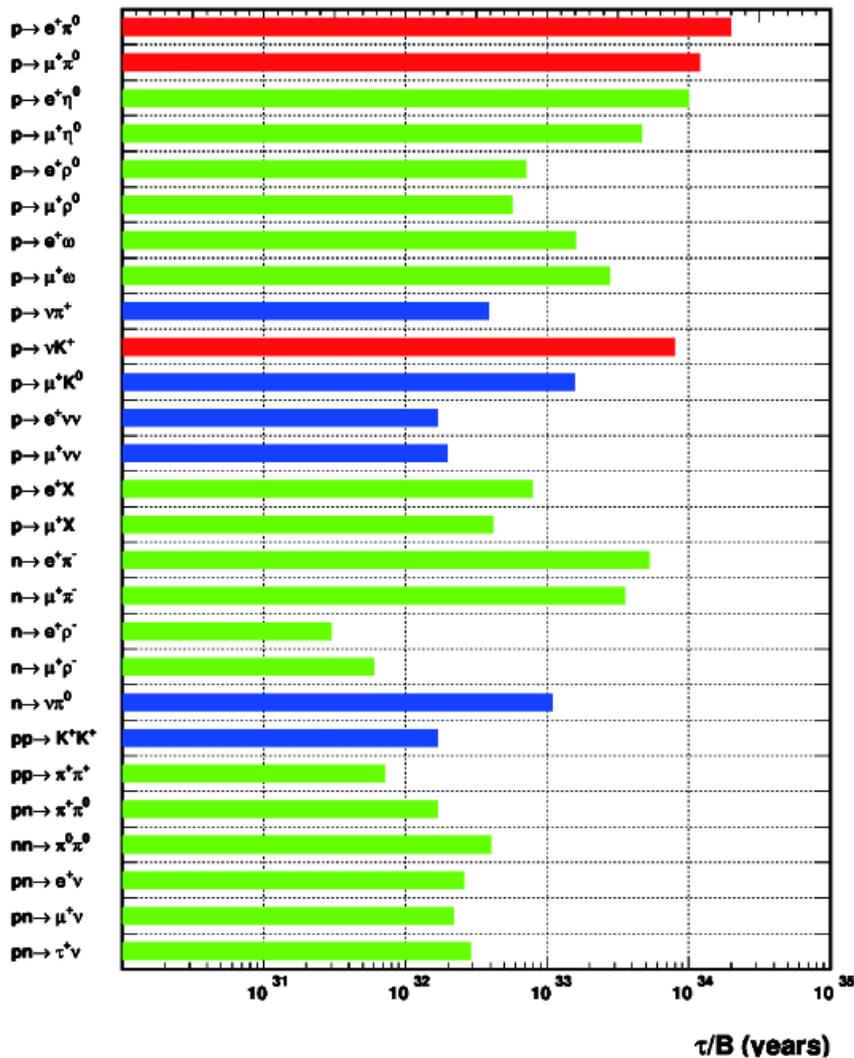

- Dominant background is  $K^+$  production by neutrino interactions.
  - $\nu p \rightarrow \nu \Lambda K^+$  ,  $\Lambda \rightarrow p \pi^-$  (BR:64 %, mostly invisible in WCD)
  - Emit nuclear  $\gamma$  as same as the signal.
- It is also rare interaction and we had poor information from very old bubble chamber. Large uncertainty.
- Recently MINERvA measures  $K^+$  production. It is very useful information for this analysis.

# 3-4. SK results (So far)

- Exposure: 365 kton · year
- Expected background: 0.3 events for  $K^+ \rightarrow \nu\mu$  with nuclear  $\gamma$ , 0.6 events for  $K^+ \rightarrow \pi^+\pi^0$ .
- No candidates observed and no excess in momentum distribution.
- Lower lifetime limit:  $> 0.8 \times 10^{34}$  year

# 3. Summary of SK results

- Most of modes have been investigated with  $> 0.3$  Mton  $\cdot$  year exposure (red and green in the left figure).
- Super-Kamiokande can cover large number of decay modes.
- Many of them are the most stringent limits on nucleon lifetime.
- We observed some candidates, but still consistent with expected backgrounds and **no evidence of nucleon decay has been observed.**

# Future prospects

- Still no evidence has been found. Major decay modes are explored up to around  $10^{34}$  years.
- Proton lives longer,  $\sim 10^{35}$  years ?
  - Run SK 10 times more ( $\sim 200$  years )? → Impossible.
- **Absolutely, we need larger detector !**

## Mass hierarchy

# Effects of unknown parameters on $\nu$ oscillation are small $\rightarrow$ Need statistics = larger detector !

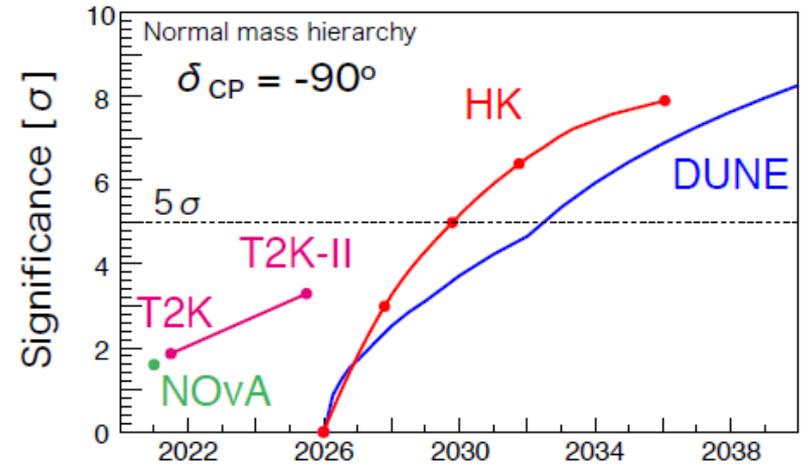

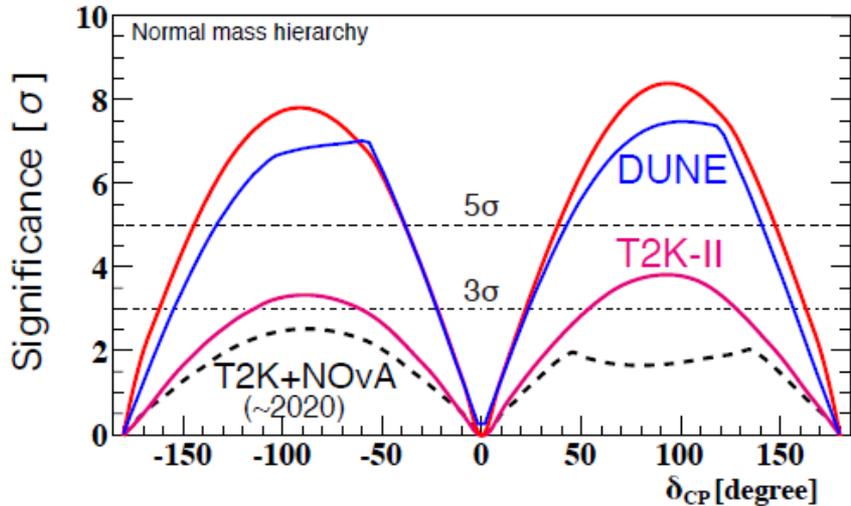

- $\nu$  beam experiments: Can study CP phase by comparing  $\nu$   $\bar{\nu}$  oscillation.

Expected  $\nu_e$  spectrum at HK (assuming 1.3 MW x 10 years)

# Sensitivity of CP violation

HK 10 years

- In 60 % region in  $\delta_{CP}$ , we can discovery  $\delta_{CP}$  with  $5\sigma$ .
- If  $= \delta_{CP} \pm 90$  degree, we can discover it within 5 years.

# Atmospheric $\nu$ : $\nu_\mu \rightarrow \nu_e$ enhancement by matter effect

$\nu_e$  oscillation due to non-zero  $\theta_{13}$  provides atm. nu. observation to investigate mass hierarch effect

$\nu_\mu \rightarrow \nu_e$  osc. probability in matter:

$$P(\nu_\mu \rightarrow \nu_e) \approx \sin^2 \theta_{23} \sin^2 2\theta_{13}^M \sin^2 \left( \frac{1.27 \Delta m_{31,M}^2 L}{E} \right)$$

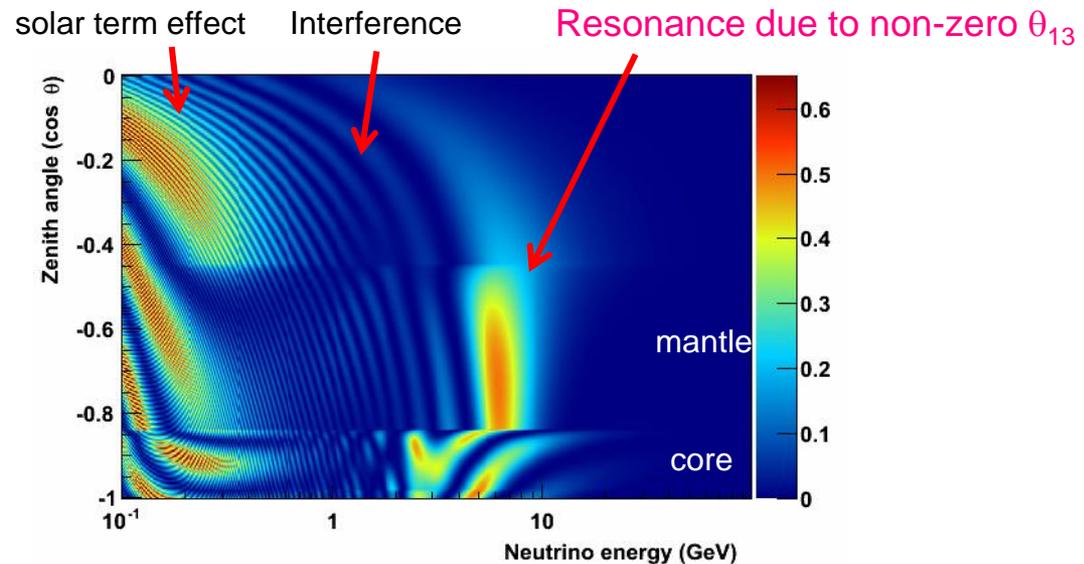

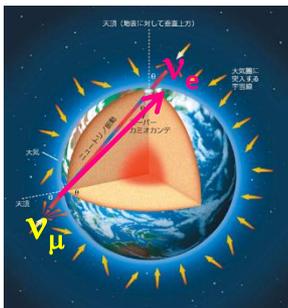

$$\sin^2 2\theta_{13}^M = \frac{\sin^2 2\theta_{13}}{\left( \cos 2\theta_{13} - \frac{A_{CC}}{\Delta m_{31}^2} \right) + \sin^2 2\theta_{13}}$$

$\sin^2 \theta_{13,M}$  has resonance feature when

$$A_{CC} \sim \Delta m_{31}^2 \cos 2\theta_{13} \quad (A_{CC} = 2\sqrt{2}G_F N_e E)$$

$\nu_\mu \rightarrow \nu_e$  resonance in multi-GeV region

$P(\nu_\mu \rightarrow \nu_e)$  of earth-throughgoing  $\nu$  :

# Occurrence of resonance feature depends on neutrino type and mass ordering:

$$\sin^2 2\theta_{13}^M = \frac{\sin^2 2\theta_{13}}{\left(\cos 2\theta_{13} - \frac{A_{CC}}{\Delta m_{31}^2}\right) + \sin^2 2\theta_{13}}$$

In case of Inverted hierarchy:

$$\Delta m^2 \rightarrow -\Delta m^2$$

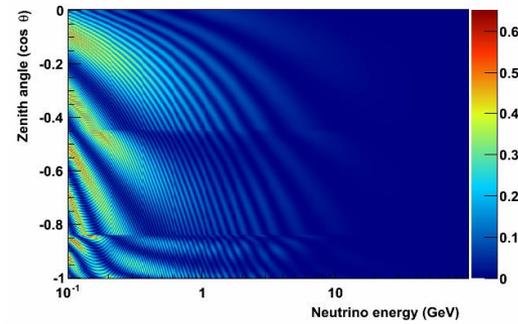

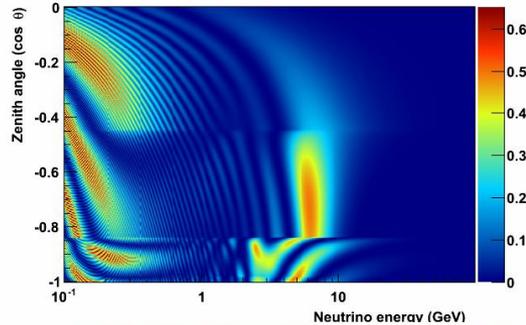

In case of anti neutrino:

$$A_{CC} \rightarrow -A_{CC}$$

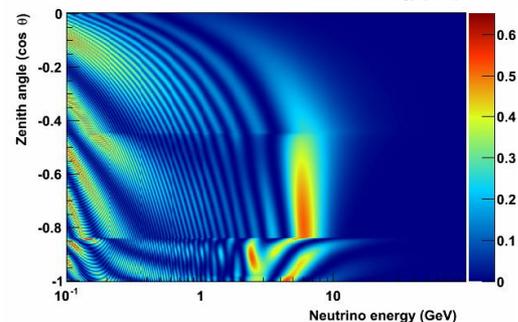

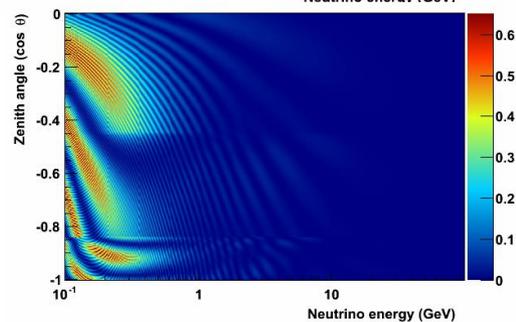

$\nu_\mu \rightarrow \nu_e$

anti- $\nu_\mu \rightarrow$  anti- $\nu_e$

Normal hierarchy

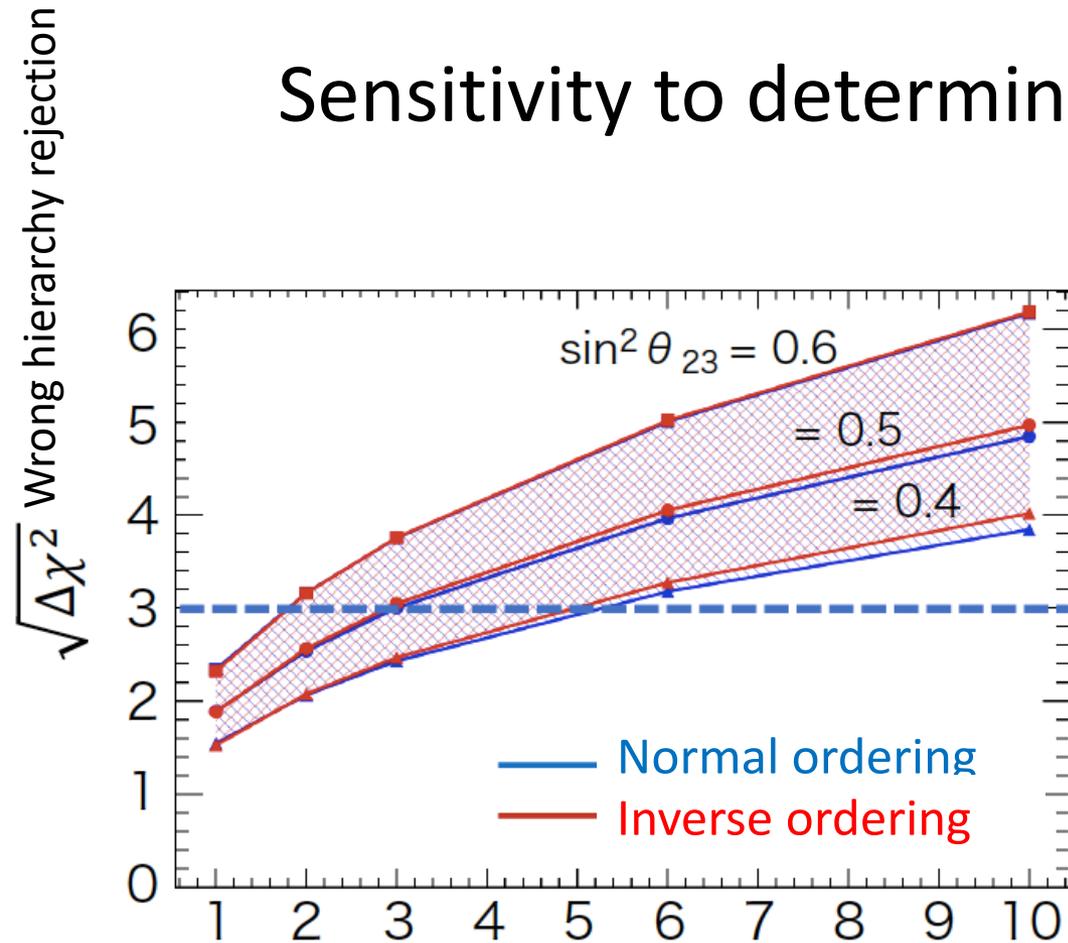

Inverted hierarchy

Possible to determine mass ordering !

# Sensitivity to determine mass ordering

**Beam  $\nu$ :** sensitive to  $\delta\text{CP}$ , but weak in mass hierarchy.

**Atm.  $\nu$ :** large uncertainty from  $\delta\text{CP}$ .

→ Combining both analysis gives **good sensitivity to mass ordering.**

**$3\sigma$  determine within 2 ~ 5 years !**

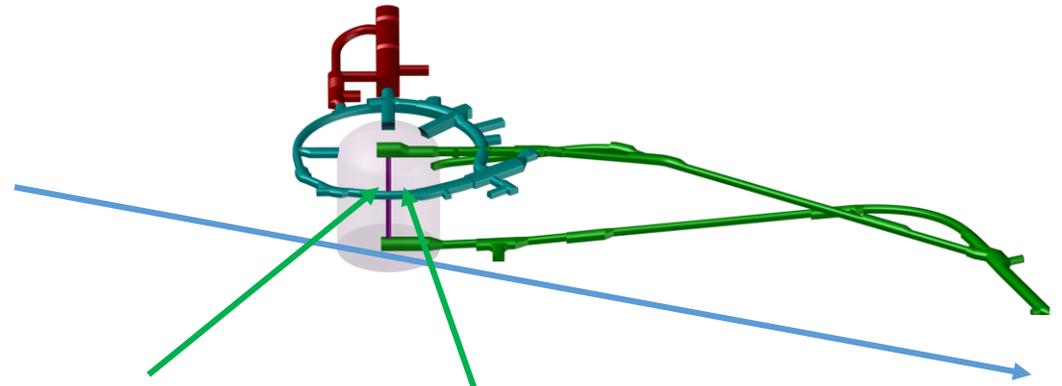

# Construction of HyperK is on-going !

Excavation is almost finished !

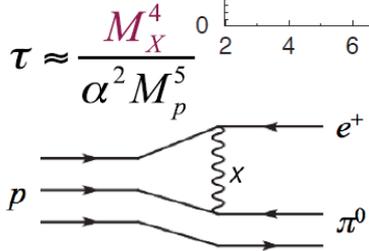

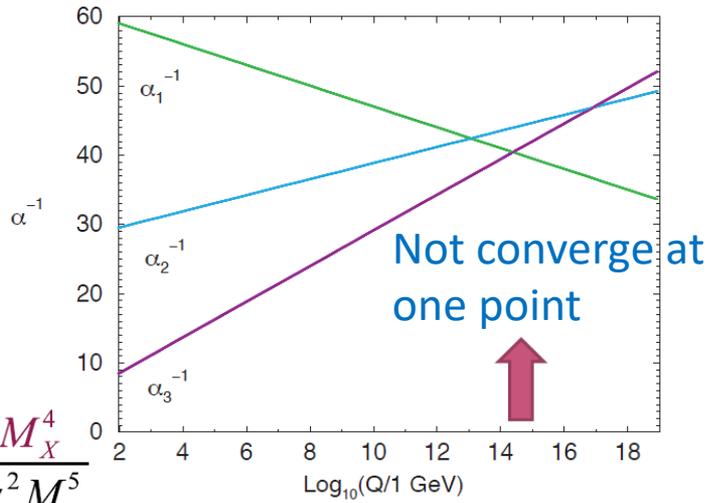

- Start construction of stainless tank in this summer.
- PMT assembly will start end of 2026.
- HK operation will start in 2028.

# 4. Summary

- Proton decay is a key phenomena of Grand Unified Theories beyond the Standard Model.
- Super-Kamiokande is the leading detector to hunt proton decays and have searched for it for more than 20 years.
- However, no evidence has been observed and the current proton lifetime limits are around  $10^{34}$  years.
- It may be around the corner ! Hope three times lucky (3度目の正直 in Japanese) in Hyper-Kamiokande.
- HK also can determine remaining  $\nu$  oscillation parameters .

dominated by the D=5 op. (color Higgs triplet,  $q=1/3$ ) mediated decays

$$\tau/B (p \rightarrow K^+ \bar{\nu}) \approx \left( \frac{0.003}{\beta_H} \right)^2 \left( \frac{M_q}{1 \text{ TeV}} \right)^2 \left( \frac{M_3}{10^{16} \text{ GeV}} \right)^2 \left( \frac{2}{\tan \beta} \right)^2 \dots$$

x  $9 \times 10^{31}$  years

( $\beta_H$  : hadronic matrix element in  $\text{GeV}^3$ )  
 $\Rightarrow$  highly model dependent

$p \rightarrow \bar{\nu} K^+$  is regarded as dominant mode in SUSY-GUTs.

# Many Other GUTs Beyond This Simple Story

Model	Ref.	Modes	$\tau_N$ (years)
Minimal $SU(5)$	Georgi, Glashow [2]	$p \rightarrow e^+ \pi^0$	$10^{30} - 10^{31}$
Minimal SUSY $SU(5)$	Dimopoulos, Georgi [11], Sakai [12] Lifetime Calculations: Hisano, Murayama, Yanagida [13]	$p \rightarrow \bar{\nu} K^+$ $n \rightarrow \bar{\nu} K^0$	$10^{28} - 10^{32}$
SUGRA $SU(5)$	Nath, Arnowitt [14, 15]	$p \rightarrow \bar{\nu} K^+$	$10^{32} - 10^{34}$
SUSY $SO(10)$ with anomalous flavor $U(1)$	Shafi, Tavartkiladze [16]	$p \rightarrow \bar{\nu} K^+$ $n \rightarrow \bar{\nu} K^0$ $p \rightarrow \mu^+ K^0$	$10^{32} - 10^{35}$
SUSY $SO(10)$ MSSM (std. $d = 5$ )	Lucas, Raby [17], Pati [18]	$p \rightarrow \bar{\nu} K^+$ $n \rightarrow \bar{\nu} K^0$	$10^{33} - 10^{34}$ $10^{32} - 10^{33}$
SUSY $SO(10)$ ESSM (std. $d = 5$ )	Pati [18]	$p \rightarrow \bar{\nu} K^+$	$10^{33} - 10^{34}$ $\lesssim 10^{35}$
SUSY $SO(10)/G(224)$ MSSM or ESSM (new $d = 5$ )	Babu, Pati, Wilczek [19, 20, 21], Pati [18]	$p \rightarrow \bar{\nu} K^+$ $p \rightarrow \mu^+ K^0$	$\lesssim 2 \cdot 10^{34}$ $B \sim (1 - 50)\%$
SUSY $SU(5)$ or $SO(10)$ MSSM ( $d = 6$ )	Pati [18]	$p \rightarrow e^+ \pi^0$	$\sim 10^{34.9 \pm 1}$
Flipped $SU(5)$ in CMSSM	Ellis, Nanopoulos and Wlaker[22]	$p \rightarrow e/\mu^+ \pi^0$	$10^{35} - 10^{36}$
Split $SU(5)$ SUSY	Arkani-Hamed, <i>et. al.</i> [23]	$p \rightarrow e^+ \pi^0$	$10^{35} - 10^{37}$
$SU(5)$ in 5 dimensions	Hebecker, March-Russell[24]	$p \rightarrow \mu^+ K^0$ $p \rightarrow e^+ \pi^0$	$10^{34} - 10^{35}$
$SU(5)$ in 5 dimensions option II	Alciati <i>et.al.</i> [25]	$p \rightarrow \bar{\nu} K^+$	$10^{36} - 10^{39}$
GUT-like models from Type IIA string with D6-branes	Klebanov, Witten[26]	$p \rightarrow e^+ \pi^0$	$\sim 10^{36}$

Uncertainties in the predictions:

Nuclear matrix elements updated w. IQCD, still: x10 uncertainty in lifetime

SUSY masses: ~ x100 uncertainty in lifetime

Proton life time:  
 $10^{30} \sim 10^{35}$  years

TABLE I: Summary of the expected nucleon lifetime in different theoretical models.

## Modes beyond $e^+\pi^0, K^+\nu$ and other antilepton + meson decays

$p \rightarrow \mu^- \pi^+ K^+$	$B + L$
$n \rightarrow \bar{n}$	$\Delta B = 2, \text{TeV} < \text{scale} < \text{GUT}$
$pp \rightarrow K^+ K^+$	$\lambda''_{uds} < 10^{-8}$
$p \rightarrow e^- \pi^+ \pi^+ \nu \nu$	6 dimensions
$n \rightarrow \nu \nu \nu$	invisible
$p \rightarrow e^+ \gamma$	radiative

there is plenty to keep us busy ...

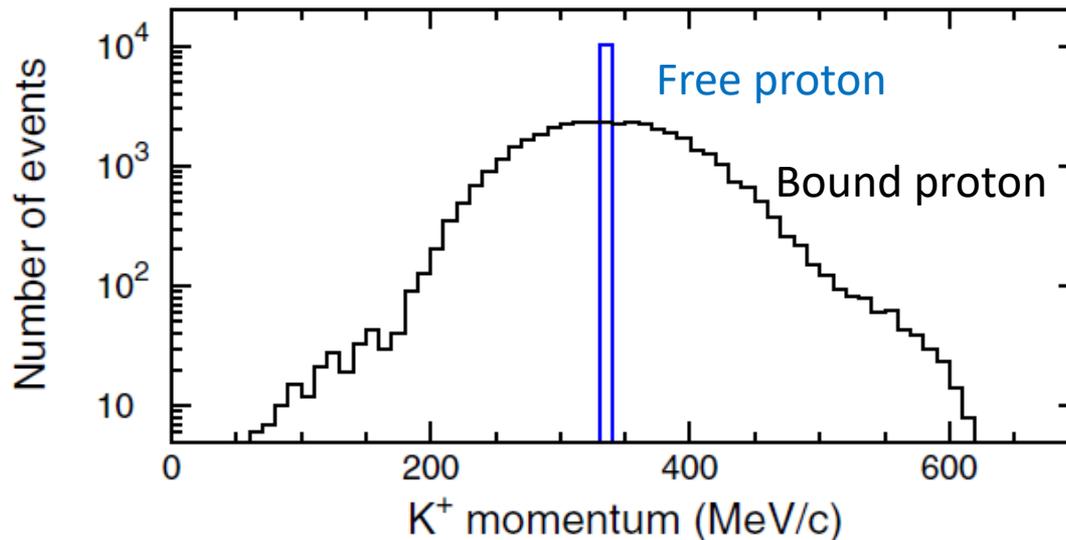

# How to find 2.2 MeV $\gamma$

- After Time-of-Flight subtraction, search for 7 hits in 10 nsec time window.  $\rightarrow$  candidates of  $\gamma$ .
- Make 16 variables related to space and time information of each hits (RMS of phi, theta, hit time, e.t.c.)
- Put them into Neural Network to judge  $\gamma$  or not.
- **Neutron tagging efficiency: 21 % (mis-tagging: 1.8 %)**

3.  $p \rightarrow \nu K^+$  search

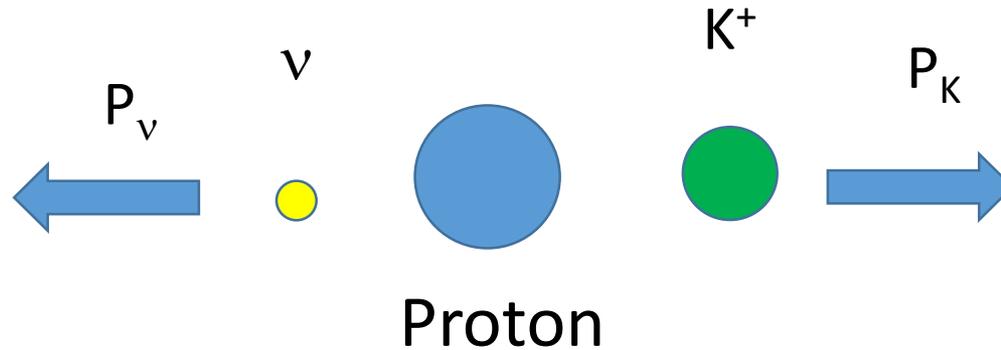

# Difficulty of $p \rightarrow \nu K^+$

- $K^+$  mass: 494 MeV, relatively heavy.
- Cherenkov threshold: 560 MeV/c.
- Most of  $K^+$  can not emit Cherenkov light.

Q. Calculate momentum of  $K^+$  from free proton decay.

Hint: proton mass: 938 MeV, "free" means proton momentum=0.

Conservation of momentum:  $P_\nu = P_K$

Conservation of energy:  $M_P = \sqrt{M_K^2 + P_K^2} + P_\nu$

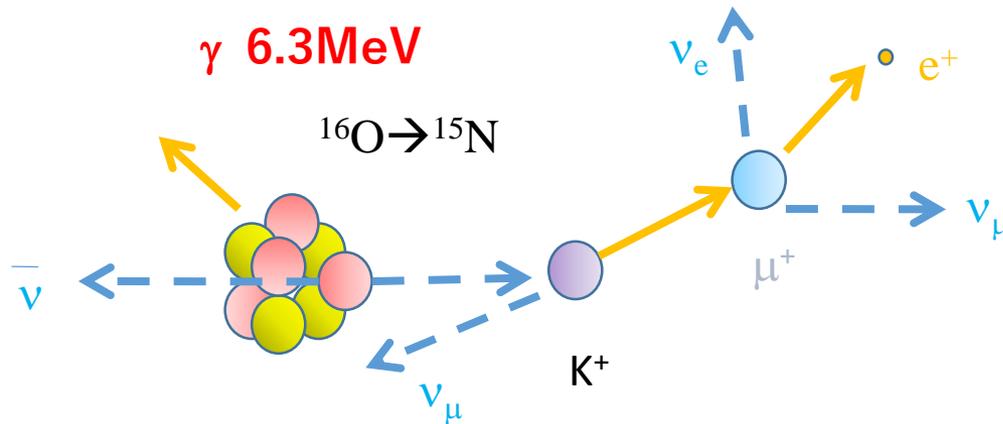

Proton                  Electron                  Neutrino

$$P_K = \frac{M_P^2 - M_K^2}{2M_P}$$

# 3-1 How to find $p \rightarrow \nu K^+$ in Water Cherenkov detector

- $K^+$  has low momentum, most of them **stop in water** and decay with 12 nsec lifetime.
- Major  $K^+$  decay mode
  - $K^+ \rightarrow \nu\mu^+$  : 64 %
  - $K^+ \rightarrow \pi^+\pi^0$ : 21 %
- “Stopping  $K^+$ ” means **two body decay products of  $K^+$  should have monochromatic momentum** as seen in the previous question !
  - $K^+ \rightarrow \nu\mu^+$  : 236 MeV/c
  - $K^+ \rightarrow \pi^+\pi^0$ : 206 MeV/c
- Using this property, Water Cherenkov detector can search for  $p \rightarrow \nu K^+$  .

## 3-2. Search for $p \rightarrow \nu K^+$ , $K^+ \rightarrow \nu \mu^+$

- Visible particle is only  $\mu^+$  with Michel electron.
- Search for data excess around 236 MeV/c of  $\mu$  comparing with atmospheric  $\nu$  MC.
- After proton decay, **40 % of remaining nucleus emits 6 MeV  $\gamma$  for deexcitation.** It is useful to reduce background.

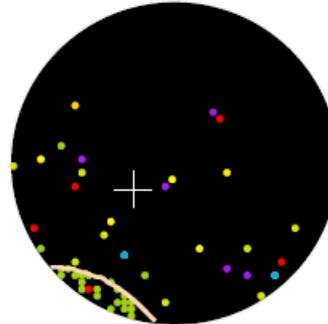

# Example of $p \rightarrow \nu K^+$ , $K^+ \rightarrow \nu \mu^+$ with $\gamma$

## Super-Kamiokande IV

Run 999999 Sub 0 Event 69  
D\_wall: 1165.1 cm  
Evis: 53.2 MeV  
mu-like,  $p = 231.0$  MeV/c

$\mu$

Color of hits corresponds to time.

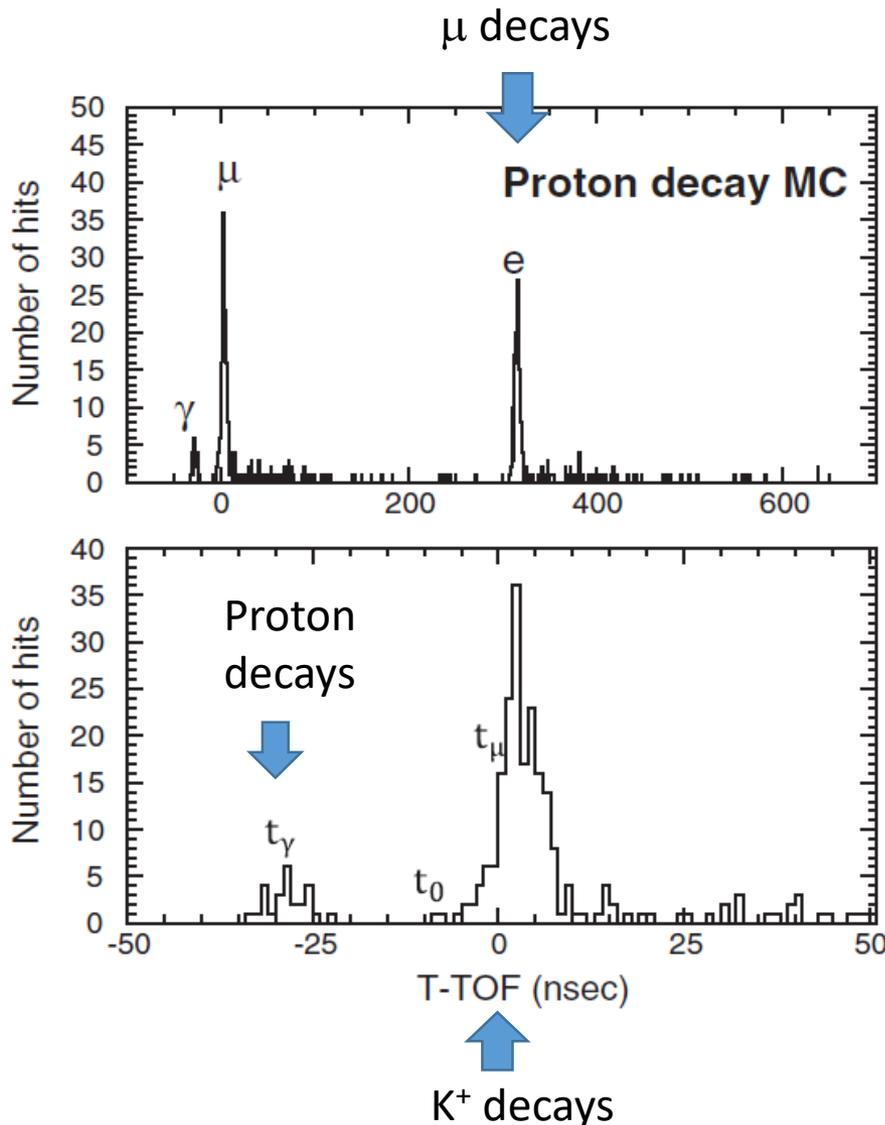

Cyan corresponds to nuclear  $\gamma$ .

Difficult to identify  $\gamma$  from hit pattern.

# Time structure with nuclear $\gamma$

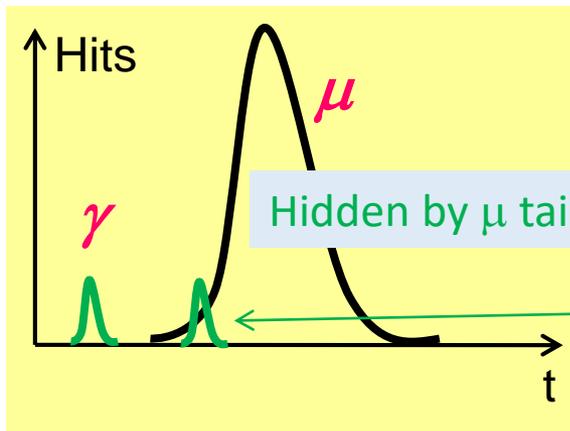

- 3 hit clusters in time should be observed in case of signal.
- The event is triggered by  $\mu$  hits.
- $\gamma$  signal is much smaller than  $\mu$  and easily hidden by tail of  $\mu$  hits.
- Make 12 nsec time window and slide it toward left from  $t_0$  (end of  $\mu$  tail) to search for maximum hit cluster.

# Selection criteria for $p \rightarrow \nu K^+$ , $K^+ \rightarrow \nu \mu^+$

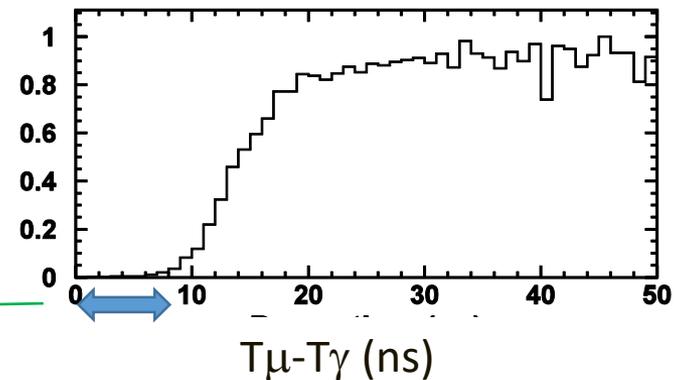

- 1  $\mu$ -like ring with Michel electron
- $215 < P_\mu < 260$  MeV/c
- Proton rejection cuts
- Search Max hit cluster  Reduce background by  $5 \times 10^{-4}$  !  
by sliding time window (12ns width);
  - $4 < N_\gamma < 30$  hits
  - $T_\mu - T_\gamma < 75$  nsec
- No neutron
- Selection efficiency = (selected events)/(proton decay in fiducial volume):  
9 %
  - $\text{Br}(K^+ \rightarrow \nu \mu^+) = 64$  %, only 40 % emits nuclear  $\gamma \rightarrow 26$  %  
even if detector is perfect.

# Remark for this analysis

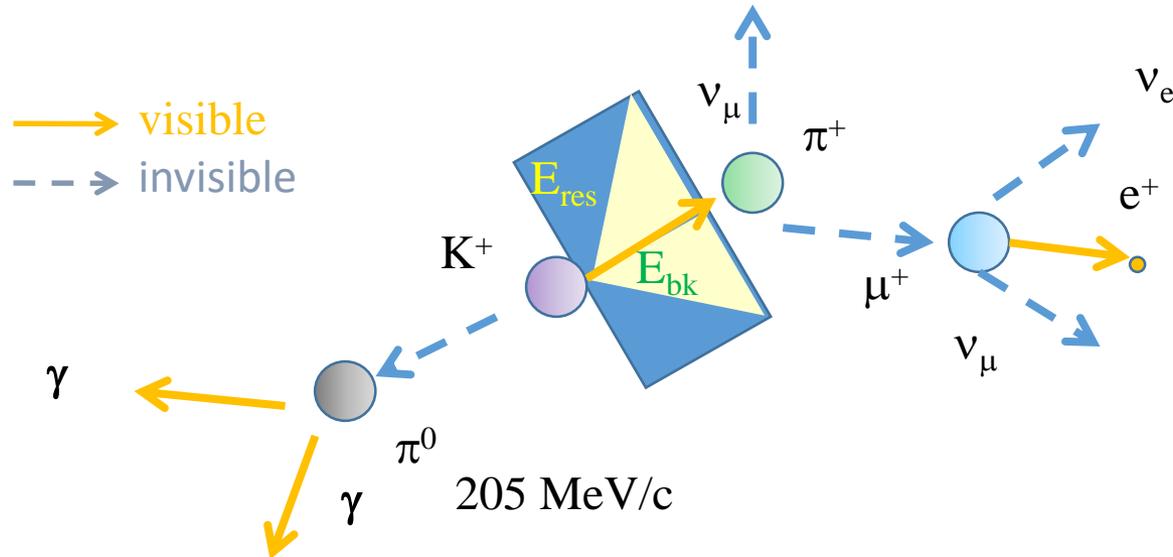

- This analysis is limited by time resolution of PMTs.
  - If  $\gamma$  is close to  $\mu$ ,  $\gamma$  peak is hidden by  $\mu$  hits.
  - Time resolution of SK PMT is 2.2 nsec at 1 photoelectron.
  - If  $\mu$  peak becomes sharper, the selection efficiency will be improved.

$\gamma$  tagging efficiency

### 3-3. Search for $p \rightarrow \nu K^+$ , $K^+ \rightarrow \pi^+ \pi^0$

- Both  $\pi^+$  and  $\pi^0$  has **205 MeV/c** in momentum. This is just above Cherenkov threshold for  $\pi^+$ , thus it is not identified as a ring in most of case.
- $\pi^+$  decays into  $\mu$  (invisible) and  $\nu$ ,  $\mu$  decays into  $e \nu_e \nu_\mu$ .
- $\pi^0$  decays into 2  $\gamma$ s.
- Search for 206 MeV/c  $\pi^0$  with Michel electron.

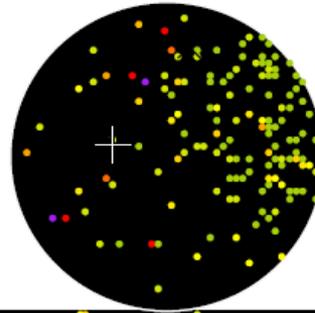

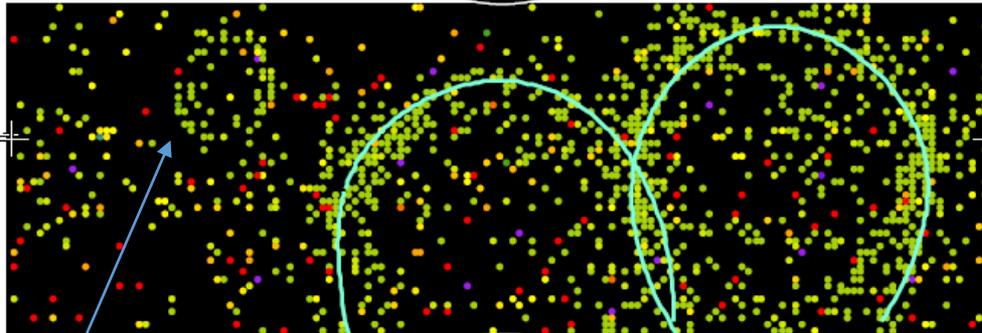

# Example of $p \rightarrow \nu K^+, K^+ \rightarrow \pi^+ \pi^0$

## Super-Kamiokande IV

Run 999999 Sub 0 Event 236

$\pi^+$

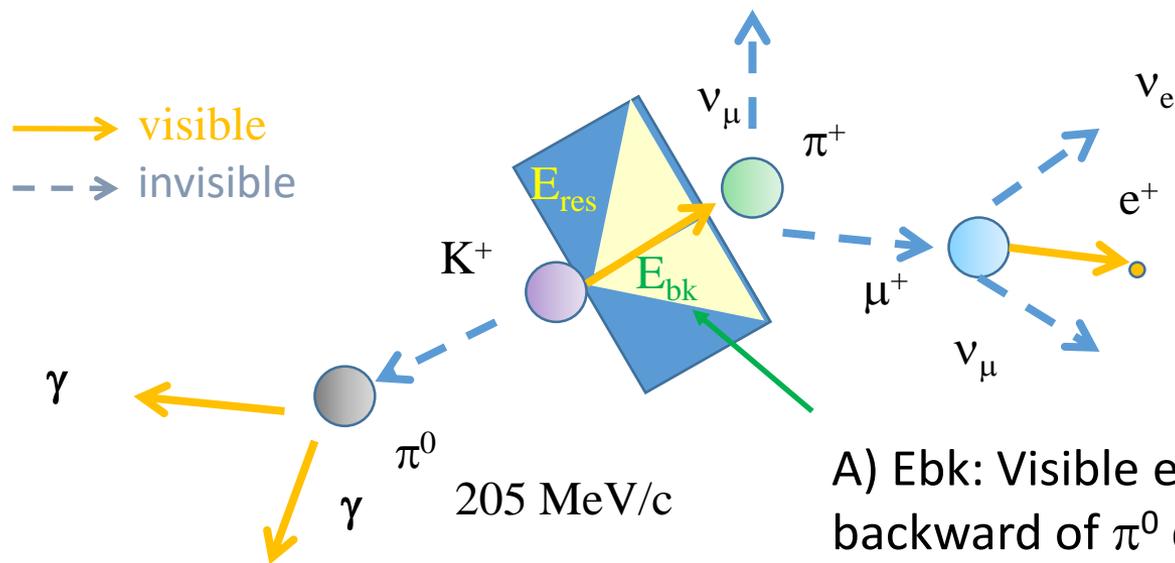

$\pi^0$

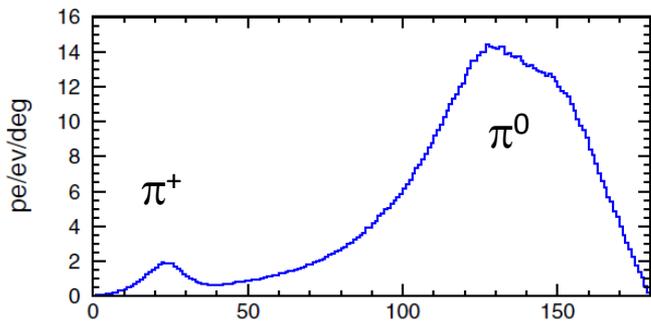

Look like a ring, but fake  
ring cut rejects this ring ...

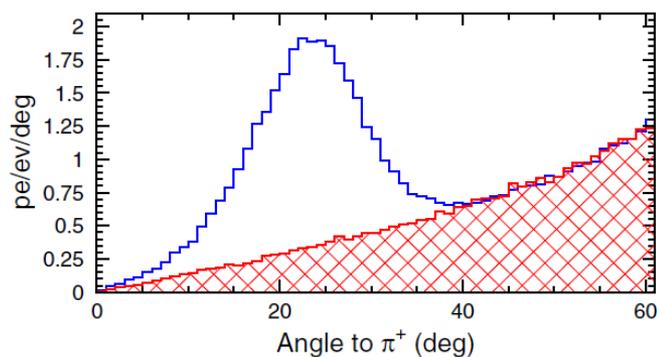

# Use $\pi^+$ information to select events

Charge distribution

Zoom

B) Make likelihood for hit pattern.

$\pi^+$  direction

# Selection criteria for $p \rightarrow \nu K^+, K^+ \rightarrow \pi^+ \pi^0$

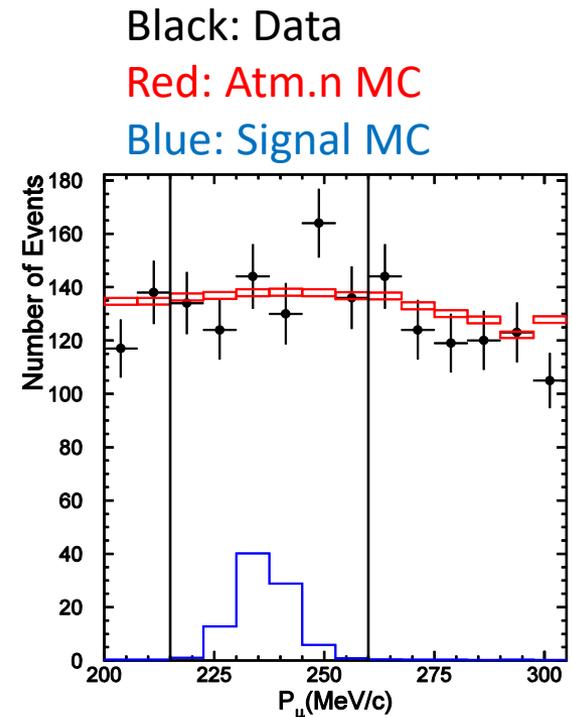

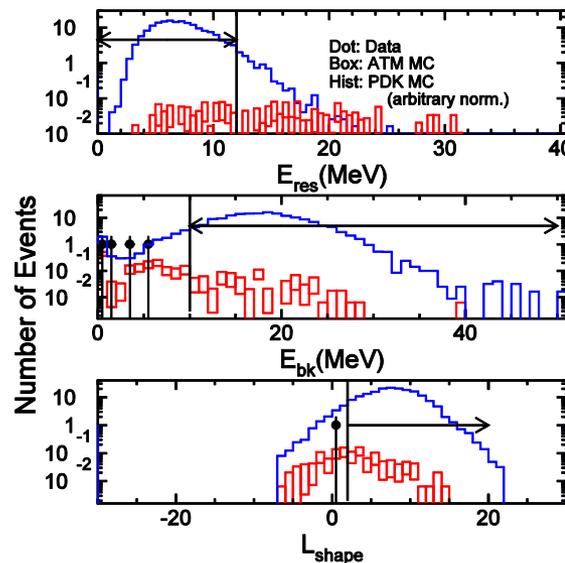

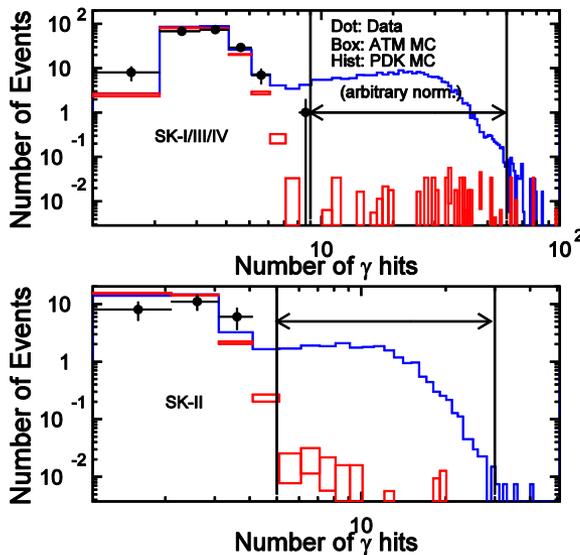

- 1 or 2 e-like rings with decay-e.
- $85 < M_{\pi^0} < 185$  MeV.
- $175 < P_{\pi^0} < 250$  MeV/c.
- $E_{bk}$ : visible energy sum in 140-180 deg. of  $\pi^0$  dir,  
 $E_{res}$ : in 90-140 deg,  
 $L_{shape}$ : Likelihood based on charge profile
  - $10 < E_{bk} < 50$  MeV
  - $E_{res} < 12$  MeV (20 MeV for 1ring)
  - $L_{shape} > 2.0$  (3.0 for 1ring)
- No neutrons
- Selection efficiency: 10 % ( $Br(K^+ \rightarrow \pi^+ \pi^0) = 21$  %)

# Background for $p \rightarrow \nu K^+$

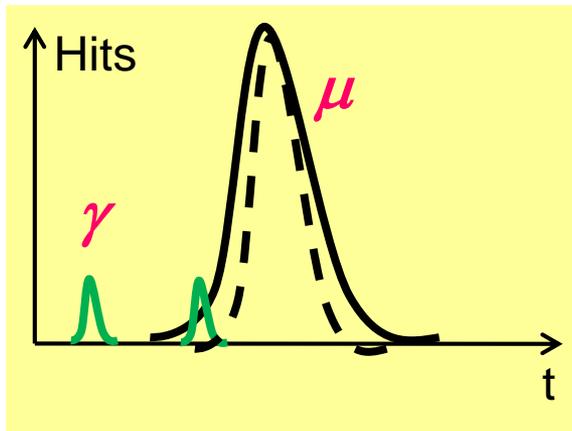

- Dominant background is  $K^+$  production by neutrino interactions.
  - $\nu p \rightarrow \nu \Lambda K^+$  ,  $\Lambda \rightarrow p \pi^-$  (BR:64 %, mostly invisible in WCD)
  - Emit nuclear  $\gamma$  as same as the signal.
- It is also rare interaction and we had poor information from very old bubble chamber. Large uncertainty.
- Recently MINERvA measures  $K^+$  production. It is very useful information for this analysis.

# 3-4. SK results (So far)

- Exposure: 365 kton · year
- Expected background: 0.3 events for  $K^+ \rightarrow \nu\mu$  with nuclear  $\gamma$ , 0.6 events for  $K^+ \rightarrow \pi^+\pi^0$ .
- No candidates observed and no excess in momentum distribution.
- Lower lifetime limit:  $> 0.8 \times 10^{34}$  year

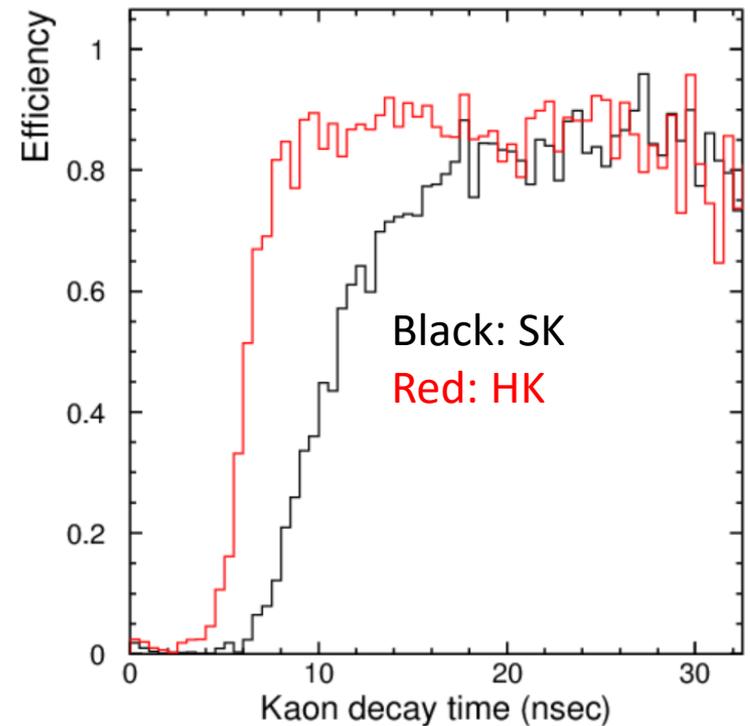

# Faster PMT response improves nuclear $\gamma$ tagging in $p \rightarrow \nu K^+$

- Time resolution: 2.2nsec (SK)  
→ 1.1 nsec (HK).
- Sharper time distribution of  $\mu$   
→  $\gamma$  close to  $\mu$  can be identified !

$\gamma$  tagging efficiency

(Better photon counting also contributes improvement)
